MALIGNANT HYPERTENSION

REPORT OF CASE TREATED BY BILATERAL SECTION
OF ANTERIOR SPINAL NERVE ROOTS FROM
THE SIXTH THORACIC TO THE SEC-
OND LUMBAR, INCLUSIVE

ALFRED W. ADSON, M.D.

AND

GEORGE E. BROWN, M.D.
ROCHESTER, MINN.

The maintained vasodilatation¹ produced by sympathectomy in the treatment of certain types of peripheral vascular diseases has stimulated us to investigate surgical procedures on the sympathetic and central nervous systems with the hope that severe forms of hypertension of young people might be controlled.

REASONS FOR TRYING SURGICAL MEASURES

In 1923 Bruning² suggested sympathectomy for the possible control of hypertension.

In the treatment of vasospastic lesions of arteries of the extremities, by sympathetic ganglionectomy and trunk resection, we have observed that the blood flow has been increased as measured in degrees of increased elimination of heat. The measurement of retinal arteries and veins by an ophthalmoscopic micrometer before and after cervicothoracic ganglionectomy shows that the caliber of these vessels has been increased by the sympathectomy³ from a third to a half the pre-operative size. Therefore we dared to postulate that it might be possible to interrupt sufficient vasoconstrictor fibers to alter the arterial tension and to prevent the sudden and paroxysmal rises, which may produce arterial rupture in the advanced stages of the disease.

We were aware that many factors are involved in the production of hypertension, but since medical measures had not offered the solution to the problem we believed that we were justified in proceeding with our surgical investigations. Whether or not our hypothesis might prove true, we also had to take into consideration the effects of sympathectomy on the function of organs deprived of their innervation in our attempt to paralyze the vasomotor control over a large vascular bed.

From the Section on Neurologic Surgery and the Division of Medicine, the Mayo Clinic.

3. Craig W. McK. and Brown G. E. Resection of the Sympathetic Nerves in Cases of Hypertension. *Proc. Staff Meet. Mayo Clin.* 8: 373-376 (June 14) 1933.

On interrupting the nerves that are involved in vasomotor control we had hoped that hypertonus of the sympathectomized arteries might be reduced and also that additional vasodilatation might take place in the same group of arteries. That is, we hoped to prepare a vascular reservoir for emergency and to avoid the sudden high rises of arterial tension.

We chose to alter the vasomotor control of arteries below the diaphragm, believing that injurious effects would not result and that the celiac and mesenteric arteries would lend themselves best to vasodilatation. It was apparent that periarterial sympathectomy would not be practical, and therefore we directed our first attack on the sympathetic rami communicantes, ganglia and trunks but later sectioned the anterior spinal roots bilaterally, from the sixth thoracic to the second lumbar inclusive, in order (1) to include all sympathetic fibers leaving by or returning through the anterior roots, thus interrupting the thoracolumbar sympathetic outflow below the fifth thoracic segment and (2) to paralyze the abdominal muscles.

By the latter procedure we hoped (1) to sympathectomize sufficient arteries to modify arterial responses (2) thoroughly to sympathectomize the suprarenal glands and (3) to remove the effects of intra-abdominal tension.

SURGICAL MEASURES TRIED

In 1925 Rowntree and one of us⁴ reported a case of malignant hypertension in which treatment was by bilateral sympathetic lumbar ganglionectomy and trunk resection, which included the second, third and fourth lumbar sympathetic ganglia and the intervening trunks. The results on the blood pressure and ultimate outcome were not significant. It was apparent that the operation did not denervate sufficient arteries to change the systemic arterial pressure and that a more extensive operation was needed. One of us (Adson) suggested and performed an extensive rhizotomy in order to include all sympathetic innervation below the diaphragm and to include the motor innervation of the abdominal muscles.

Aug. 6, 1930 a patient with malignant hypertension was subjected to bilateral section of the anterior and posterior nerve roots from the sixth thoracic to the second lumbar, inclusive, through an approach afforded by laminectomy. The reasons for suggesting this procedure were that (1) the blood pressure always dropped and the vasopressor reactions were inhibited following spinal anesthesia, (2) the patient under consideration presented vasodilatation of the arteries of the hand and fingers following block anesthesia by procaine of the cervicothoracic ganglia, in spite of organic hyper-

4. Rowntree L. G. and Adson A. W. Bilateral Lumbar Sympathetic Neurectomy in the Treatment of Malignant Hypertension. *Report of Case J. A. M. A.* 85: 959-961 (Sept. 26) 1925.

trophy of the medial coats of the arterioles and (3) this patient exhibited sharp hypertensive crises, with subjective symptoms and with inordinate increases in the blood pressure, which should theoretically be inhibited by denervating the splanchnic circulation

In view of the progressive character of the hypertension and the short expectancy of life, the patient elected the operation even though informed that the muscles of the abdomen and lower costal muscles would be inactive, and that it would be necessary for him to wear an abdominal support. These facts previously had been learned from a case in which extensive rhizotomy had been performed by one of us (Adson) for gastric crisis of tabes. In the case in which operation was performed Aug 6, 1930, ether anesthesia was used. During the early part of the operation the systolic blood pressure often rose higher than 200 mm of mercury, but at the close of the operation it had dropped to 100 mm. The diastolic pressure dropped from 120 to 90 mm. The

completely sympathectomized. The results were variable, and in the severe type of hypertension not as much was accomplished as was hoped for.

The reduction and inhibition of the crises of blood pressure effected in the initial case in which rhizotomy was performed encouraged us to employ extensive rhizotomy again, with the view of controlling the severe form of hypertension.

REPORT OF CASE

A woman, aged 29, was first seen at the clinic in 1923, at which time she complained of headaches and high blood pressure of eighteen months' known duration. On admission the blood pressure, in millimeters of mercury, was 228 systolic and 156 diastolic. There was no evidence of renal disease. The retinal arterioles were constricted. The hourly readings of blood pressures taken under resting conditions varied from 150 to 200 systolic, and from 100 to 150 diastolic. The patient's diet was restricted, following which the headaches were relieved.

The patient returned to the clinic in 1933 because of marked fatigue, headaches, palpitation and dyspnea. The headaches usually were of the frontal type, but at times they were occipital on her arising in the morning. The blood pressure on admission was 240 systolic and 165 diastolic, the pulse rate was 120 beats per minute, and the heart was enlarged to grade 3. There was a soft systolic murmur in the mitral area. The retinal arteries were sclerosed, graded 2, with angiospasm, new and absorbing hemorrhages, and a few cotton-wool exudates were present in each eye, these are the features of retinitis of severe hypertension of group 3, the borderline malignant form of hypertension.⁷ Hourly readings disclosed a variation in systolic blood pressure of from 180 to 230 mm of mercury and in diastolic pressure of from 110 to 160 mm. With the cold pressor test the blood pressure was increased to 280 systolic and 180 diastolic. The value for urea was 28 mg per hundred cubic centimeters of blood. The value for sulphates was 5 mg per hundred cubic centimeters of serum. Albumin was not present in the urine, but there were occasional casts. The electrocardiogram disclosed a diphasic T wave in derivation III. The basal metabolic rate was +23. The diagnosis was essential, early malignant type of hypertension without renal insufficiency.

Operation was performed Oct 10, 1933, under ether anesthesia and was not attended with any unusual incident. It included bilateral section of anterior nerve roots from the sixth thoracic to the second lumbar, inclusive. The posterior roots were not sectioned, and the second lumbar anterior root on the right was found to be incompletely sectioned. The purpose of the operation in this case was to interrupt all thoracicolumbar sympathetic fibers below the sixth thoracic segment thus paralyzing vasoconstrictor nerves below that level, including the sympathetic supply to the suprarenal glands and in addition, paralyzing the abdominal muscles further to reduce intra-abdominal tension. This was accomplished with the possible exception of the right second lumbar root. During the early part of the operation the blood pressure rose to 250 mm systolic and 178 diastolic. Ether anesthesia undoubtedly was responsible for the rise, but the subsequent marked fall to 80 systolic and 50 diastolic could scarcely be accounted for by the effects of shock for there was practically no loss of blood during the laminectomy. From our previous experience, extreme care was taken to avoid injury to the small arteries and veins on the roots during the dissection and resection of the anterior roots, and to insure hemostasis. Postoperative convalescence was uneventful. The wound healed by primary union and no complications arose. The patient had no disturbance of micturition or of defecation. The motor powers and sensation of the extremities remained normal. The muscles of the abdomen were relaxed, but since the patient was of asthenic type there was no sagging or bulging. The patient did complain of a slight drawing sensation

Fig 1—Blood pressure and response to the cold test with changes in posture

operation otherwise was uneventful except that it required considerable time to complete, as every precaution was employed to insure hemostasis, in spite of this, postoperative bleeding developed and necessitated opening of the wound. The blood pressure one month after operation varied from 140 to 160 systolic and from 80 to 110 diastolic. The headaches and crises of paroxysmal hypertension had disappeared. One year later this control was still effective. Changes in the spinal cord developed following the hemorrhage, and it has been difficult to continue with controlled physiologic studies which explains the absence of previous reports.

Subsequently Pieri⁵ and later Craig,⁶ developed a procedure that permitted resection of the major and minor splanchnic nerves and the first lumbar ganglion. This procedure was divided into two stages. In the first stage the nerves on the one side were resected and in the second stage those on the opposite side. The procedure did not include the ramus to the second lumbar ganglions, therefore the suprarenal glands were not

in the region of the left loin the first three or four days when she was up in a chair, but this disappeared when an abdominal support was applied. The patient was dismissed from the hospital at the end of four weeks but remained under observation for another week in order that physiologic studies might be made.

SUBSEQUENT OBSERVATIONS

Hourly readings of the blood pressures were made the day following operation. The mean levels were 100 mm of mercury systolic and 70 mm diastolic. The second day the blood pressure had increased to 170 systolic and 130 diastolic. It remained at approximately this level when the patient was recumbent. Thirty-one days after operation the mean levels of blood pressure, with the patient recumbent, were 180 systolic and 125 diastolic. The range was from 155 to 195 systolic and from 100 to 150 diastolic. The response to cold when the patient was recumbent raised the blood pressure to 220 systolic and to 155 diastolic. At this time the patient had resumed her normal activity.

Fig. 2—Sweating and surface temperatures of fingers and toes thirty-five days after operation.

remained at approximately 130 (fig. 1). The response to cold with the patient sitting gave a maximal value of 190 systolic and 142 diastolic. With the patient standing, the blood pressure varied from 150 to 162 systolic and from 120 to 135 diastolic. The response to cold when the patient was standing, gave a maximal increase to 186 systolic and 145 diastolic. With the sharp drop in the systolic blood pressure, when the patient was standing, the patient did not experience any subjective symptoms. The pulse rate increased twenty beats per minute.

Passive changes of posture on an adjustable table gave the following readings: recumbent, 190 systolic, 140 diastolic; head down at an angle of 90 degrees, 200 systolic, 142 diastolic; head up at an angle of 90 degrees, 168 systolic, 120 diastolic.

Sweating—Thirty-five days after operation, demarcation of the sweating zone was determined by placing the patient in a sweating cabinet. Cobalt blue test papers were used to detect the nonvisible degrees of perspiration. No visible sweating was found below the level of the epigastric notch in front or of the angle of the scapulae in the back. Faint degrees of sweating were found in isolated areas on the skin of the upper part of the abdomen (fig. 2).

Surface Temperatures of Lower Extremities—The temperature of the skin of the right and left toes was significantly different. The average for all digits of the right foot was 31.7 C., and that for the digits of the left foot, 33.7 C. The difference in surface temperature was noted both objectively and subjectively and is probably explained by the incomplete division of the second right lumbar anterior root.

Renal Function—The patient was given 200 cc of water and the bladder was emptied at the end of one hour. Excretion of water was 60 per cent when the patient was recumbent and 10 per cent when the patient was standing. There was no difference in the amount of phenolsulphonphthalein excreted whether the patient was standing or recumbent.

Retinal Arteries—The retinal arteries were still definitely narrowed. Sclerosis was present in most of the vessels. There was one definite cotton-wool exudate in the left retina. Retinitis was much less active than when the patient was admitted.

Untoward Effects Following Operation—Some weakness of the abdominal muscles was noticed by the patient when she stood. She had some difficulty in assuming the sitting position. There was no objective bulging of the rectus abdominis muscles. It was found that the drop in the blood pressure when the patient stood was less marked after a snug abdominal support had been applied (fig. 3).

COMMENT

The patient whose case is here reported in detail had a severe, progressive form of essential hypertension. Organic changes in the retinal arterioles, and active retinitis were present. The length of life in this type of case after such changes have been noted, as has been shown by Keith,⁸ is usually less than three years. One month following resection of the anterior spinal

Fig. 3—Drop in blood pressure less with abdominal support. The pressor reaction to cold is increased.

nerve roots there was a definite drop in blood pressure more marked in the systolic than the diastolic when the patient was recumbent, but this lowering of pressure was accentuated by the upright posture. In this position there was, for this patient, relative hypotension. It is obvious that restoration of this patient's diastolic blood pressure to normal levels would be impossible.

⁸ Keith, N. M., Barker, N. W., and Kernohan, J. W. Histologic Studies of the Arterioles in Various Types of Hypertension. *Tr. A. Am. Physicians* 46: 66-68, 1931.

because of the structural hypertrophy of the arterioles. While this patient is active and up and about, the range and variation of her blood pressure are those of a moderate degree of hypertension, and during this active period the overload on the heart and other organs is materially diminished. It is probable that this decrease in the pressures during a larger portion of the period of twenty-four hours should be of great benefit. The argument often advanced, that high levels of blood pressure of patients with hypertension should be maintained for the kidneys to function adequately, is not demonstrated in this case. The activity of the heart and kidneys is well maintained, with a drop of 80 mm of mercury in systolic pressure. The excretion of water was not materially modified but was merely delayed, and this was only an exaggeration of what occurs among normal subjects when they are recumbent. A change in the size of the arterioles of the retina could not be demonstrated in this short period, but decrease in the activity of the retinitis was noted. The effects of the operation on the pressor reactions to cold were of interest. It has been shown that this pressor response is comparable to the effects of psychic and emotional stimulation on the blood pressure. It constitutes an accurate measuring rod to determine effects of treatment on variability of blood pressure. Following operation there was a significant decrease in the maximal rise in blood pressure. This was more marked when the patient was upright, namely, there was a decrease of 100 mm of mercury in the response of the systolic pressure. This effect was further confirmed by the postoperative hourly readings of blood pressure taken under various forms of mental and physical activity. Denervation of the vessels below the diaphragm of the patient did not completely inhibit the pressor responses to cold, this may be the effect of the vasoconstrictor response of the arteries of the upper part of the body. The effects of the operation on the sweat and vasomotor fibers indicated that almost complete degeneration of the sweat fibers had taken place below the level of the episternal notch. It is probable that the depressor effects of this operation were the result of two factors: (1) loss of vasomotor control of the splanchnic and peripheral arteries below the diaphragm, and (2) lowering of intra-abdominal pressure by paralyzing the abdominal muscles.

The favorable results of this operation in so severe a form of hypertension are most encouraging, and its further use for younger patients with severe progressive forms of essential hypertension seems justified.

Wheals—We know that an urticarial wheal can be produced in normal persons by the injection of histamine, morphine and innumerable other substances and also by localized mechanical, thermal or electrical injury. We also know that in patients with serum sickness hay fever, asthma and eczema the intradermal injection of the substances to which they are sensitized produces a wheal although these substances have no such effect on normal skin. The serum of allergic subjects will often locally sensitize the skin of normal persons so that it in turn will react to subsequent injection of the allergen or, in some instances, to absorption of the allergen after it is swallowed. The investigations of Philippon, Lewis, Blackley, Frausnitz and Küstner, Walzer and others have established these facts and added greatly to our knowledge of the pathogenesis of wheals. There remains, however, a gap between our understanding of the mechanism of wheal formation and our information as to the causes of the general eruptions of wheals which we refer to as urticaria. Urticaria is a symptom of many diseases.—Hopkins, J. G., and Kesten, B. M. Urticaria—Etiologic Observations. *Arch. Dermat. & Syph.* 29: 358 (March) 1934.

SUBTOTAL BILATERAL SUPRARENALECTOMY FOR HYPERSUPRARENALISM

(ESSENTIAL HYPERTENSION)

JOSEPH L. DeCOURCY, M.D.

CARROLL DeCOURCY, M.D.

AND

OTTO THUSS, M.D.

CINCINNATI

Down to the present time, a study of the vaso-regulatory mechanism would indicate the futility of an attempt to pick out and burden one single link of the chain and place the responsibility on this for alterations of the whole system. This does not mean, however, that a better understanding of the whole problem could not be arrived at if one of these links was studied with particular care.

The heart and the peripheral vessel system must decide the issue. Both are under the regulation of nervous influences, which either act directly on the cardiac and vascular musculature and on the contractile elements of the capillary walls or are brought to bear on them indirectly through the mediation of hormones. The part played by the blood electrolytes in determining the effect of the hormone concentration is also a deciding factor.

In our studies, this being a preliminary report, an attempt is made to cut down the suprarenal hormone concentration of the blood, confining our observations at present to the so-called essential hypertension group. The treatment of essential hypertension, associated with little or no arteriosclerosis and no kidney destruction, has presented apparently insuperable difficulties to the internist. Little of permanent value has been accomplished in these cases, and they usually go on to a fatal termination. We have felt for some time that the picture is one of an endocrine dyscrasia and that the responsible glands are the suprarenals. We know that the secretion of the medulla of the normal suprarenal raises the blood pressure, and it is reasonable to assume that the increased secretion contingent on an abnormal suprarenal might give the symptom of so-called essential hypertension.

Assuming that essential hypertension is due to excessive secretion of epinephrine by hyperplastic suprarenals, comparable to the excessive secretion of thyroxine in hyperplastic thyroids, we have attempted to reduce the secretion by subtotal suprarenalectomy in a number of cases, the results of which will be shown in this paper.

Of all the endocrine glands, the one about which the most is known is the thyroid. This is, in fact, due to its accessible position. While we would not imply that the last word has been said regarding the thyroid, it is well known that in certain pathologic states there is an increased secretion of its normal thyroxine, and it is known that the resulting symptomatology, with its tachycardia, tremor, vasodilatation, loss of weight, increased basal metabolic rate and the like is due to the increased secretion circulating in the blood stream. It is also known that the disturbance of the thyroid gland itself which causes the hypersecretion is one of hyperplasia. What causes the hyperplasia of the thyroid is as yet only a matter of conjecture, but there is evidence

supporting the view that the vegetative nervous system plays an important role in it.

The suprarenal, because of the large network of nerve fibers connected with its capsule, has been called the brain of the vegetative nervous system. It seems logical, therefore, to find an analogy between the overactivity of the thyroid, due to sympathetic stimulation causing hyperthyroidism, and the overactivity of the suprarenals, due to sympathetic stimulation causing hypersuprarenalism. If this analogy is valid, partial suprarenalectomy should give results in hypertension comparable to those obtained from thyroidectomy for hyperthyroidism.

In all our cases of hyperthyroidism in which an operation has been performed and which later exhibited recurrent symptoms of hyperthyroidism we have been able to show an increase in the remaining hyperplastic tissues and have accordingly relieved our patient by again lessening the amount of the remaining tissue. In one case, partial thyroidectomy was performed no less than five times with eventual complete relief of symptoms and restoration of a normal basal metabolic rate.

Crile¹ has felt that even in these cases the suprarenal has been the activating influence and reports relief of symptoms through severing of the afferent nerves of the suprarenal gland. We ourselves performed suprarenal denervation in six cases of neurocirculatory asthenia with very indifferent results. In this disease there is almost always a normal or slightly lowered blood pressure, both systolic and diastolic. We believe, however, that in cases of hyperthyroidism the attack should be made on the thyroid itself, whenever possible. But even in pure hypersuprarenalism, denervation as performed by Crile does not seem to us to be sufficient, probably because a hyperplasia of the gland already exists, just as cervical sympathectomy was unsatisfactory in hyperthyroidism, and for the same reason.

Pende's² experimental denervation of a suprarenal gland in a kitten from which the other suprarenal had been removed two months previously resulted, six months later in a well maintained cortex and a completely atrophied medulla, but here there was no question of an existent hyperplasia, the organ being practically normal when denervation was done.

REPORTS OF SUPRARENALECTOMY IN THE LITERATURE

A glance over the literature reveals but few cases in which the attempt has been made to reduce essential hypertension by partial suprarenalectomy.

Galata³ and Antonucci in 1929 removed one entire suprarenal from a woman in a desperate condition with a systolic blood pressure of 300 mm of mercury, after all attempts at relief by medicinal measures had failed. The blood pressure fell in the first three days after operation to 210 and then remained more or less stable around 200, with disappearance of most of the associated symptoms. Another report six months later showed that this improvement had been maintained.

Monier-Vinard and Desmarest⁴ in 1930 reported the removal of the right suprarenal from a woman who had

suffered for ten years with intolerable hypertensive symptoms, from the time of the menopause. In this case recourse was had successively to spinal anesthesia, suprarenalectomy, radiotherapy and lumbar puncture. The removal of one suprarenal reduced a blood pressure of 320 systolic, 140 diastolic to 220 systolic, 110 diastolic, where it became stabilized for three months, after which it returned to the former figures.

Pieri⁵ in 1932, after trying the effects of resection of the right or left splanchnic nerves in five cases of essential hypertension, tried suprarenalectomy in two cases, removing in each case one entire gland. In the case of a man, aged 63 with a systolic pressure of 230 mm (Pachon), there was a very slight postoperative drop followed by a rapid rise soon afterward although the clinical symptoms were almost totally relieved, tachycardia on effort and a sense of thoracic pressure disappearing completely. At the end of twenty-two months the blood pressure exceeded 280 mm (Pachon). In the second case no improvement at all was observed, a blood pressure of 225 (Riva-Rocci) being exactly the same five months later.

On the other hand the experience of a larger number of writers in connection with the surgical removal of pheochromic tumors of the suprarenal, revealed clinically by attacks of paroxysmal hypertension, throws a different light on the subject. Eisenberg and Wallerstein⁶ found fifty-three cases of these tumors in the literature, one half of which were accompanied by hypertension, before the tumors were removed. After removal, the hypertensive attacks and all their associated symptomatology—omitting, tachycardia, dyspnea, and the like—ceased abruptly.

Cases of this kind have been reported, notably by Oberling and Jung,⁷ C. H. Mayo,⁸ Pincoffs,⁹ Shipley,¹⁰ Wilder,¹¹ Rabin,¹² and Labbe, Tinel and Doumer.¹³ Wilder¹¹ regards this as without doubt the most important evidence thus far obtained in support of the view that certain forms of hypertension may be due to the secretion of excessive amounts of epinephrine. Rabin¹² found thirty more or less similar cases in the literature, the most suggestive being those in which the hypertension produced by the tumors was paroxysmal.

The completeness with which all symptoms disappeared in these cases when the hyperplastic tissue responsible for hyperfunction of the gland was removed supports my view that the most rational method of treatment of essential hypertension is the surgical excision of sufficient amounts of glandular tissue to relieve the excessive functioning of the gland itself.

PROCEDURE

The operation of partial suprarenalectomy as performed by us consists of removal of about two thirds of each suprarenal and is done in two stages. The por-

tion removed includes both medulla and cortex and is taken from the part of the organ remote from the entrance of the blood vessels

The approach is made from the back through a kidney incision, the kidney being held down with a special retractor. The suprarenal must be recognized and stripped clean of all fat and overlying structures. The portion to be removed is then clamped and excised, the raw surface being covered with a continuous lock-stitch chromic suture.

Spinal anesthesia is employed, and the blood pressure is watched closely throughout the entire operation. If the fall is more than anticipated, ephedrine is promptly given and intravenous saline solution with epinephrine administered in case of collapse. These patients, however, seem to tolerate spinal anesthesia very well, and to date we have not observed any alarming symptoms.

The operation is not severe and, aside from accidents, we consider it a safe surgical procedure.

REPORT OF CASES

CASE 1—Mrs E. M., a woman, aged 27, married a nullipara, admitted to the clinic, Oct 7 1933, complained of frequent vomiting spells with fullness of the head and dizziness. She said she had been confined to bed for two months previous to observation.

The family history was negative for goiter, carcinoma and tuberculosis. The mother and father were living and well. The patient started to menstruate at 13 years, the periods being irregular, often from six to eight months apart. She had had the ordinary diseases of childhood. There had been no operations.

On examination the patient was well developed and appeared acutely ill, severely nauseated and weak. There were no gross abnormalities of the skin; the mucous membrane was pale and the skin was hot and dry. The pupils were equal, reacting to light and in accommodation. The

sclerae and conjunctivae were negative. The ears and nose were normal on external examination. The lips were dry, the tongue was moderately coated. The breath was slightly fetid, its odor suggestive of acetone. The pharynx was red. The upper teeth were artificial, the remaining lower ones in fair condition. The neck was symmetrical. The thyroid was normal to inspection and palpation. Adenopathy could not be found.

The chest was symmetrical. Respiratory excursions were full and equal, negative to percussion and auscultation. The first sound at the apex, bounding and forceful in the fifth interspace, was slightly outside the nipple line. The rate was rapid and the sound not clear but replaced by a slight systolic murmur that was transmitted to the axilla. The second sound at the aortic area was tympanic in quality. The breasts were normal. The abdomen was symmetrical. No masses or tenderness could be felt. The liver and spleen could not be pal-

pated. No hernia was present. Reflexes were equal and sluggish. There was no edema of the extremities. The blood pressure was 245 systolic, 150 diastolic. Urinalysis in the morning showed specific gravity, 1006; albumin, negative; sugar, negative. In the afternoon specific gravity, 1022; albumin, negative; sugar, negative.

Microscopic examination was negative.

The basal metabolic rate was plus 24. The kidney function showed normal dilution and concentration. The Wassermann reaction of the blood was negative. The red blood cells numbered 4,800,000. The differential count was normal. Urea nitrogen was 15 mg. The blood sugar was 120 mg two hours after a meal.

We have given a rather comprehensive history to show that we were dealing with so-called essential hypertension. It should also be borne in mind that the patient had been confined to bed at her home 25 miles from Cincinnati for two months previous to the examination.

On admission she was given dextrose to overcome the acidosis. October 17, ten days later, the first operation was performed, which consisted of the removal of three-fourths of the left suprarenal under spinal anesthesia.

Before the spinal anesthesia was given the blood pressure was 260 systolic, 150 diastolic.

The systolic blood pressure readings during the operation were (starting operation) 9 17 a.m., 220, 9 23 230, 9 30 180, 9 32 140, (end) 9 47 220.

October 18, the day following the blood pressure was 176 systolic, 130 diastolic, October 19 174 systolic, 115 diastolic, October 20, 170 systolic, 130 diastolic, October 22, 164 systolic, 114 diastolic.

The second operation was performed, October 23, at which time three-fourths of the right suprarenal was removed.

October 25 the blood pressure was 172 systolic, 110 diastolic. October 26, three days after operation, the blood pressure was 165 systolic, 108 diastolic.

It is interesting to note that the patient's diastolic blood pressure did not go below 140 during her long period of bed rest (over two months) previous to operation but dropped to 108 three days after the second operation and has continued to fall to the time of writing.

CASE 2—Miss A. C. aged 55, single, a nurse, complained of headaches and dizziness. The father had died at 60 of pneumonia, the mother died at 72 of senility.

Five years previous to entrance to the hospital, the patient was refused life insurance because of high blood pressure, although at that time she was feeling well. About one year later she began having severe, persistent headaches with dizziness. Later these attacks were accompanied by hot and cold flashes. Cardiac action became forceful, accompanied with shortness of breath.

The menopause occurred at 52. The blood pressure on the patient's entrance to the hospital was 230 systolic, 140 diastolic. The patient was rather obese. The basal metabolic rate was plus 28.

Urinalysis in the morning showed specific gravity, 1008; albumin, negative; sugar, negative. In the afternoon it showed specific gravity, 1017; albumin, negative; sugar, negative.

The Wassermann reaction of the blood was negative. Nitrogen was 14.6 mg. Nonprotein nitrogen was 31.26 mg.

Left suprarenalectomy was performed Nov 21, 1933; right suprarenalectomy was performed December 1.

A pheochromocytoma of the size of a marble was found in the left suprarenal. Slides of both suprarenals showed lipoidosis of the cortex with medullary hyperplasia.

Immediately following the first suprarenalectomy the diastolic pressure dropped to below 100 mm of mercury and has remained there to date. At the last reading, December 17, the pressure was 150 systolic, 82 diastolic.

In six cases in which we have operated to date, exploring twelve glands, cortical tumors were present twice.

Chart 1—Drop of blood pressure following bilateral subtotal suprarenal ectomy. The spinal anesthesia had entirely worn off before these drops occurred. A, right suprarenalectomy; B, left suprarenalectomy.

COMMENT

According to Goldzieher,¹⁴ who has conducted experimental studies on the suprarenals for more than twenty years, the removal of an entire gland followed later by partial resection of the second gland, does not interfere in the least with the well being of the animal operated on. He found that not more than a fourth of one gland is needed to keep an animal alive indefinitely, and the Christians¹⁵ insist that life can be maintained on even less than this.

It has been our own experience that patients tolerate perfectly the removal of from two thirds to three fourths of each gland, a suitable period for recovery being allowed to elapse between the respective procedures on the two individual organs.

The view that hypertension is the result of pathologic changes in the suprarenals was first suggested by Josue¹⁶ and by Vaquez,¹⁷ both of the French school, in 1904. Vaquez dared on the basis of a case that he had studied anatomically, in which a patient with hypertension was found to have a hyperplastic suprarenal on one side, to formulate the hypothesis that "hypertension is caused by substances capable of provoking excessive vasoconstrictor phenomena, and that these can be discovered only in certain products elaborated by the glands of internal secretion and, in particular, by the suprarenal capsules."

Schur and Wiesel¹⁸ in 1907, expressed the view that there is a close connection between the problem of epinephrine formation and an associated hypertrophy of the suprarenal gland in all states attended with increased blood pressure, and that this is revealed not only by a chemically demonstrable increased epinephrine content but also morphologically by an increase of chromaffin substance, by the appearance of extensive cell connections in the suprarenal medulla and by multiplication of immature medullary cells.

In 1909, Philpot,¹⁹ after a study of twenty-seven cases of hypertension, reported that the suprarenal medulla was enlarged in nearly every case.

In the last decade, however, the view that pathologic changes of the suprarenals had any connection with hypertension was generally discounted by laboratory workers. Dietrich and Siegmund,²⁰ after a survey of the literature, considered the existence of a true medullary hypertrophy as still a debated question. Although admitting that there had been isolated cases of this phenomenon, they regarded these as exceptional and concluded that, whereas hyperplasia of the cortex is common enough, the medulla is very little subject to hyperplasia and that no relationship can be discovered between the development of medullary substance and any bodily condition or constitutional disease.

Recently, however, on the basis of new and comprehensive studies, Goldzieher²¹ has summarized, as follows, the accumulating evidence pointing to changes in

the medulla that serve as the forerunners of hypertension: (1) increased epinephrine content of the glands in states of hypertension, as demonstrated by Ingier and Schmorl²² and by Goldzieher,²¹ (2) hypertrophy of the musculature of the suprarenal veins demonstrated by Goldzieher and Sherman²³ and by Allen,²⁴ (3) morphologic changes of the suprarenal cortex²⁵ and diffuse hyperplasia of the suprarenal medulla.²⁶

Thus, Allen²⁴ observed in cases of hypertension that there was hypertrophy of the muscles of the suprarenal veins, which he thought in all probability indicated increased functional activity, the result of sympathetic overactivity. He found that the veins of the gland have in cases of hypertension, a ratio of muscle to lumen twice as great as that in cases of normal blood pressure, which theoretically would indicate (1) increased function of the suprarenal glands (2) over

Chart 2 (case 2)—Initial drop secondary rise and maintenance of low diastolic pressure A date of admission B left subtotal suprarenalectomy, spinal anesthesia C right subtotal suprarenalectomy spinal anesthesia D date of dismissal

activity of the sympathetic nervous system, and (3) the effect of noxious substances in the blood stream. The fact that the total area of the lumens of all the suprarenal veins is greater in cases of hypertension than in those with normal blood pressure shows that there is a higher degree of vascularization in the former, which, according to Allen, probably indicates a higher level of functional activity. In his opinion, these observations are distinct evidence of a close relationship between increased functional activity of the suprarenal glands and a state of hypertension.

Similar studies conducted by Goldzieher and Sherman²³ showed that both the muscle of the central vein and the single muscle bundles of the small venules participate in the hypertrophy. Injection of the suprarenals through the central veins in patients with hypertension revealed a different distribution of the injected dye from that observed in the controls.

The fact that it was not possible to demonstrate by laboratory methods the presence of epinephrine in the arterial blood has been used as a clinching argument by the opponents of this view of a relationship between medullary pathologic changes and phenomena of hypertension. "No one," admitted Shipley¹⁰ in 1929, "has proven up to the present that an increase of epinephrine is found in the blood in patients with hypertension. Many clinical observations in patients with chromaffin cell tumors indicate that this is true, but the proof has not been forthcoming."

Very recently, however, Kure²⁷ and his co-workers have found a new method by which this demonstration has at last been accomplished. By strictly excluding oxygen, which destroys epinephrine, from the blood during the taking of the measurements, they succeeded in demonstrating the presence of the vasoconstrictor substance in the arterial blood. They found that the substance cannot be measured until it is present in amounts in excess of 1/2,500,000 in the whole blood, that oxygen destroys it, that addition of hydrochloric acid increases it, and that it is present in larger amounts in the arterial blood of hypertonic than in that of normal individuals. The substance was always present in the arterial blood in rather high degree, but not in standing blood nor in venous blood. Reasoning that, if hypertension in essential hypertonia is produced by hypersuprarenalinemia, this excess must inevitably be decreased by administration of atropine, which inhibits its liberation into the blood, these workers were able to demonstrate by actual measurements that this decrease occurs after such administration of atropine.

It is therefore finally established in the laboratory that human arterial blood contains epinephrine and that this epinephrine is found in increased quantities in the blood of hypertensive subjects.

Goldzieher²¹ has lately drawn attention to the occasional finding of hyperplastic nodules in the pheochromine tissue of the suprarenal. He reports four such cases, in all of which there was either a present state of hypertension or indications of an earlier condition of this kind. The nodules were quite comparable to the nodular growths characteristic of hyperplastic processes in other glandular organs. The appearance of this nodular hyperplasia in addition to diffuse hyperplasia in subjects with hypertension or a history of past hypertension again raises the question whether their occurrence is only incidental here or might be expected with some degree of regularity. Since hyperplasia of other glandular organs has been regarded ordinarily as adequate morphologic evidence of their increased function, it seems unnecessary to look for further proof that the same relations hold true for the suprarenals.

Taking all the evidence into account, we feel, therefore, that the establishment of a clear relationship between essential hypertension and overproduction of epinephrine, comparable to that existing between hyperthyroidism and oversecretion of thyroxine, justifies our contention that the most logical way to reduce essential

hypertension is to reduce the amount of superfluous secreting tissue in the suprarenal gland itself.

The case studies of partial suprarenalectomy that we have carried out have been so uniformly satisfactory that we feel that we are now relieving patients who previously were doomed to die, and we are accordingly publishing this report with the hope that the work will be carried on by others in carefully selected cases.

CONCLUSIONS

1 An analogy exists between the overactivity of the suprarenals, due to hypersuprarenalism, and the overactivity of the thyroid, due to hyperthyroidism.

2 Partial suprarenalectomy gives results in hypertension comparable to the results of thyroidectomy in hyperthyroidism.

3 In some of our cases, partial suprarenalectomy relieved all symptoms of hypertension.

4 There is a relation between hypersuprarenalism and hypertension, in states of essential hypertension it is always possible to demonstrate hyperplasia of the suprarenal medulla.

NEGATIVE EFFECT OF PROLONGED ADMINISTRATION OF OVARIAN SUBSTANCES IN HEMOPHILIA

RICHARD P. STETSON, MD

CLAUDE E. FORKNER, MD

WILLIAM B. CHEW, MD

AND

MURRAY L. RICH, MD

BOSTON

The attempt to treat hemophilia by ovarian extract is not new. As early as 1904, Grant¹ recorded clinical improvement in a patient with hemophilia following the administration of small amounts of an ovarian extract. Wright² in 1909, mentioning possible means of combating this inherited defect, skeptically commented on the possibility of administering ovarian extract to male bleeders "with a view of endowing them with the mysterious physiological advantage which, in bleeder families, attach to the female sex." In 1923 Hynes³ suggested that the production of antithrombin was controlled by the internal secretions of the sex glands. He reported normal clotting of hemophilic blood following injection of corpus luteum. B and M Gonzalez-Alvarez⁴ in 1925 and Samson-Himmelstjerna⁵ in 1926 discussed the theoretical possibilities of treating hemophilia by ovarian extract. Neihans⁶ in 1930 treated two hemophilic patients with ovarian implant and observed improvement following the implantation of ovary without corpus luteum, whereas no benefit followed the implantation of whole ovary.

Recent interest in the treatment of hemophilia with estrogenic substance has been stimulated by the reports

of Birch.⁷ She has reported nineteen cases of hemophilia in which from 15 to 80 grains (1 to 5 Gm) daily of ovarian preparations was given subcutaneously, intramuscularly and orally over long periods of time.^{7c} In nine of these patients she observed a good response to ovarian therapy, in nine others a definite but less marked improvement and in one no obvious response. In these cases the effect was both general, as shown by an increase in weight, vitality and hemoglobin, and specific, as shown by a decrease in the number and severity of the hemorrhages and a lowered blood coagulation time. Foord and Dysart,⁸ Kimm and Van Allen,⁹ and White¹⁰ have reported immediate cessation of hemorrhage and diminution of coagulation time following the intramuscular injection of ovarian extract or estrogenic substance. Kugelmass¹¹ has observed that while therapy with the female sex hormone preparation "produces no change in the concentration of the clotting substances from the levels characteristic of hemophilic subjects" and has not diminished the tendency to bruising, it has decreased the tendency to bleeding following natural trauma and has diminished periodic effusions. Key,¹² without presenting specific data, felt that the condition of two cases of hemophilia he studied was not influenced by the administration of ovarian extract. Bernstein¹³ reported symptomatic relief in two hemophilic patients after the intramuscular injection of small amounts of whole blood from menstruating women. He states that ovarian extract had been given previously to these patients without change in their joint disorders. Blaylock,¹⁴ in reporting the amputation of an arm of a patient with hemophilia, mentioned the daily subcutaneous administration of an ovarian preparation obtained from the fetal fluid of cattle. One week later, the coagulation time of the blood was slightly longer than before ovarian therapy was instituted.

More recently, Brown and Albright¹⁵ have reported the treatment of a 42-year old hemophilic patient with injections of two preparations of estrogenic substance over a period of three days without significant change in the coagulation time. Estrogenic substance was demonstrated in the urine of this patient before treatment and in greatly increased amounts during the administration of the hormone.

The theory that has prompted these repeated attempts to control hemophilic bleeding and blood-clotting mechanisms by the administration of ovarian extracts and the estrogenic factor is not without a certain speculative attraction. The generally accepted belief, substantiated by studies of cytologists and geneticists, is that the character of inherited traits depends on the character and behavior of the chromosomes. Inherited traits may be sex linked, sex limited or independent of

sex. The work of Wilson, Morgan, and other students¹⁶ of the subject has shown that in human beings the male has only one X-chromosome, whereas the female has two. Certain traits including such conditions as hereditary optic atrophy, color blindness and hemophilia are believed to be transmitted in the X-chromosomes. These conditions are called sex-linked defects in distinction to cases of simple heredity, in which the determiners are located in other chromosomes. Certain traits such as the growth of facial hair, are also independent of the X-chromosomes but are termed sex-limited characteristics, owing to the influence exerted on them by hormones from the sex glands. It is improbable that the administration of potent ovarian substance or of estrogenic substance could exert a fundamental influence on the existence of hemophilia. It is logical to speculate whether or not the bleeding manifestations of the disease might be inhibited temporarily by providing the hemophilic male with substances that can be demonstrated in females and normal males but lacking in males with hemophilia. Such a substance, if effective at all conceivably might act either on the circulating blood to produce an immediate and transient effect or on the faulty elements of the blood of hemophilic patients at their site of formation, thus to produce a delayed and probably more prolonged effect.

Birch^{7b} has reported the production of estrus in rats injected with extracts of the urine of normal men, whereas no estrus was produced in rats injected with extracts of the urines of seven hemophilic males and of two transmitters (females) of hemophilia. From these observations she concluded that the urine of hemophiliacs is lacking in estrogenic substance. To be of undoubted significance these results must be confirmed in every case of proved and active hemophilia so tested. The demonstration of estrogenic principle in an undoubted case of hemophilia would tend to disprove the responsibility of that substance for the immunity to hemophilic manifestations possessed by females. Contrary to Birch's observations the estrogenic factor has been demonstrated consistently in the urines of five of our patients (no estrogenic factor determinations were carried out in cases 4 and 7) in amounts usually greater than those contained in the urines of normal males.¹⁷ Brown and Albright¹⁵ also found estrogenic substance in the urines of their hemophilic patient before treatment.

The present communication reports the results observed in seven hemophilic patients either fed large quantities of ovarian tissue or given by mouth or parenterally various extracts of ovary and estrogenic substance for from four to eleven weeks.

These patients exhibited classic manifestations of hemophilia dating from infancy or early childhood, and in each instance there were other male members in the family who were affected similarly. Their ages varied from 14 to 36 years. All had suffered repeated hemorrhages into their joints with resulting deformities and limitation of motion of one or more joints. Morphologic examination of the blood in no case revealed significant abnormalities except a slight degree of hypochromic anemia. Blood platelets in each case were normal or increased in number. Three of the seven patients (patients 1, 2 and 5) had been treated in 1931

17 The content of estrogenic substance of the urine was determined by Drs G V and O W Smith in the Fearing Research Laboratory of the Free Hospital for Women Brookline Mass. These results will be reported subsequently.

with large amounts of liver without objective benefit, as reported by Marlow¹⁸

METHODS AND MATERIALS USED

In determining the blood coagulation time, both venous blood and capillary blood were used. All determinations were carried out at room temperature. A modification of the method of Lee and White¹⁹ was used for the venous blood. Five cubic centimeters of

of capillary blood obtained from puncture of an ear lobe was determined by means of a capillary tube in the same manner as for venous blood.

The coagulation times of the venous and capillary blood from our patients were determined at frequent intervals during the administration of the following preparations of ovarian substance or estrogenic substance, which were given for various periods of time as indicated, and as recorded in the charts:

- 1 Theelin, orally to patients 1 and 2
- 2 Soluble ovarian substance intramuscularly to patient 4
- 3 Ovarian substance-desiccated whole ovary, orally to patient 3
- 4 Fresh ground raw whole beef ovary (a small residue of connective tissue was discarded) orally to patients 1 and 4
- 5 Aqueous extract from fresh whole beef ovary, orally to patient 2. This extract was prepared by adding from 200 to 400 cc of water to ground ovaries and shaking in a mechanical shaker for two hours at room temperature. After straining the juice expressed in the grinding was added to the aqueous extract for administration.
- 6 The solid residue of ovarian tissue after water extraction, orally to patient 1
- 7 Ovarian substance, orally to patients 1, 5 and 6
- 8 Theelin subcutaneously to patients 3 and 7

RESULTS OF TREATMENT

It is evident from a study of the accompanying charts that no significant changes occurred in the coagulation time of either the venous or the capillary blood of these patients which could be attributed to any one of the various forms of ovarian substance or estrogenic substance administered. Six of the patients received large amounts (quantities are shown in the charts) of one or another form of ovarian substance for from twenty-eight to eighty-one days. Patient 7 received theelin subcutaneously while in a severe bleeding phase, which terminated fatally in three days.

Chart 1—Observations on the blood coagulation time in case 1 while ovarian therapy was being given

blood was drawn from an arm vein into a syringe that had been rinsed previously with physiologic solution of sodium chloride, care being taken to cause as little admixture of tissue juice as possible. One cubic centimeter of this blood was dropped into each of five test tubes 8 mm in diameter, which also had been rinsed with physiologic solution of sodium chloride. The first tube was tilted at intervals of fifteen minutes until it could be inverted without its surface contour being disturbed. This procedure was then carried out on each succeeding tube until all could be inverted without having fluid run at the surface. This end point was recorded as the time of surface coagulation. At this time the blood cells, which had settled to the bottom of the tube, still continued to flow when the tube was tilted. The period of observation was continued until the sediment of cells showed no motion when the tube was tilted. This was recorded as the time of complete coagulation. These two end points are very close together normally and widely separated only when delayed coagulation of the blood is present or when the cells have settled before the first solid clot forms. They can be distinguished readily in normal blood if it is centrifugated rapidly for two or three minutes before clotting occurs.

The coagulation time of venous blood in a capillary tube was determined also. For this determination a tube 10 cm long and approximately 1 mm in diameter was nearly filled by capillary attraction with venous blood immediately after withdrawal. At intervals of five minutes the capillary tube was tilted and the movement of the column of blood was observed. When the movement became sluggish, pieces were broken from the end of the capillary tube at intervals. The time at which a fibrin thread could be drawn out of the tube was considered the end point. The coagulation time

Chart 2—Observations on the blood coagulation time in case 2

Patient 1 received 0.4 mg (200 rat units) of theelin by mouth daily for a period of nine days, and then 0.8 mg (400 rat units) daily for eighteen days, with no significant reduction in the coagulation time of his venous blood. Chart 1 shows the variations in the coagulation time of his blood immediately following this twenty-seven day period when, over a period of eighteen days, he was given the residue after aqueous extraction of 3,980 Gm of ovary, a daily average of residue derived from 221 Gm of whole ovary. This

18 Marlow A. The Negative Effect of the Administration of Liver in Hemophilia. Bull. Johns Hopkins Hosp. 49:49 (July) 1931.
19 Lee R. I. and White P. D. A Clinical Study of the Coagulation Time of Blood. Am. J. M. Sc. 143:495 (April) 1913.

was followed by the administration of a total of 5,989 Gm of fresh, raw ground, whole ovary over a period of thirty-two days an average of 187 Gm a day. These combined periods covered eighty-one days during which not only did his coagulation time fail to diminish but he suffered one spontaneous hematoma and two hemarthroses.

Patient 2 (chart 2) received a total of 4,800 rat units of theelin by mouth over an eleven day period after

average of 193 Gm. The coagulation time was unchanged.

Chart 5 shows the complete coagulation times of the venous blood observed in cases 1, 5 and 6 during the administration of ovarian substance by mouth over periods of forty-four, seventy, and forty-one days respectively. The usual daily dose of 8 Gm of this substance is reported by the manufacturer to be the approximate equivalent of 48 Gm of the fresh glandular substance. These periods of observation started eleven weeks after patient 1 had received the treatment shown in chart 1 and ten weeks after patient 5 had received anterior pituitary-like principle from the urine of pregnancy for seven days. Patient 6 had received no ovarian therapy previously.

In case 6 the coagulation times of one hour and on the following day of four hours observed eighteen weeks after therapy was stopped, were shorter than any observed during or immediately following treatment. Coagulation times of five hours and four hours and thirty-six minutes were observed six months after treatment. Six days after the last observation of the coagulation time in case 1 recorded in chart 5 it rose to seven hours and forty-five minutes to fall a week later to three hours and fifty-five minutes a level identical with that observed on the thirty-fifth day of treatment.

During these periods of observation all three patients were excreting estrogenic substance in amounts varying from less than 2 rat units to 12 rat units per forty-eight hour quantity of urine. In no case was there any demonstrable correlation between the amount of estrogenic substance excreted and the coagulation time of the blood.

An additional patient (patient 7) who was bleeding severely was given a total of 5 cc (250 rat units) of theelin in three intramuscular injections over a three-day period. This resulted in no apparent effect on his bleeding. In spite of repeated blood transfusions and injections and local applications of a thromboplastic substance and hemostatic serum, he continued to bleed and died from hemorrhage.²¹

Chart 3—Observations on the blood coagulation time in case 3

which he was given the aqueous extract derived from 5,521 Gm of ovaries over a period of thirty days, a daily average of extract derived from 184 Gm of whole ovaries. In view of the occurrence of a hemarthrosis, it did not seem justifiable to deter the administration of horse serum to which he had been sensitized previously. As shown by Eley and Clifford²⁰ and also by Marlow,¹⁸ this procedure has little or no effect on the coagulation time of venous blood but shortens the clotting time of capillary blood, and it was thus not a probable factor in the shorter coagulation time of the venous blood observed after its administration.

Patient 3 (chart 3) was given desiccated ovarian substance orally, 2 Gm for one day, 3 Gm on the second and third days, 4 Gm on the fourth day, and thereafter 6 Gm daily for twenty-four days. This total amount, given over a period of twenty-eight days, is reported by the manufacturer to be derived from 936 Gm of whole ovary, making a daily average derived from 33.4 Gm of the gland. Six months after the period shown in chart 3, the patient was given 1 cc (50 rat units) of theelin subcutaneously daily for seven days. During the latter period the coagulation time of the venous blood dropped from ten hours to seven hours and thirty-four minutes. One week after the treatment was discontinued, the coagulation time was six hours. Although this is a 40 per cent decrease in the coagulation time, it is no greater a drop than is seen frequently without therapy and does not seem attributable to therapy with estrogenic principle in view of the continued drop after theelin was omitted.

Patient 4 (chart 4), after the daily intramuscular injection of 1 cc of soluble extract of ovarian substance for eighteen days and 2 cc daily for the subsequent four days, received orally 6,189 Gm of whole raw ground ovary over a thirty-two day period, a daily

Chart 4—Observations on the blood coagulation time in case 4

COMMENT

The amount of ovarian substance given in six of these cases of hemophilia was greater than any recorded in the literature given in similar cases. The periods of observation would seem long enough to demonstrate any change in coagulation time that such therapy might effect. The fluctuations of blood coagulation time observed are of a magnitude encountered frequently in hemophilic patients under no specific form

²⁰ Eley R. C. and Clifford S. H. Hemophilia. Treatment by Protein Sensitization. Am J Dis Child 42: 1331 (Dec) 1931.

²¹ Acknowledgment for permission to include this case is gratefully made to the Third Medical Service (Tufts) of the Boston City Hospital.

of therapy, as was demonstrated in these cases during control periods. Case 1 has been observed for twenty-four years, cases 4 and 5 have been observed for six years. During these years when various forms of treatment were given or when no particular treatment was given, the fluctuations of the blood coagulation time have been fully as great as has been recorded during the present series of observations. In no case in which ovarian therapy was given did the coagulation time of the venous blood approximate a normal figure.

In two instances (cases 3 and 7) the subcutaneous injection of estrogenic substance (theelin) for from three to seven days failed to produce any immediate effect on the coagulation time in either case or on the severe bleeding in case 7.

Three of our patients felt that they were subjectively improved by treatment. Patient 5 gained 29 pounds (13.2 Kg) while in the hospital. However, none of our patients showed objective evidence of improvement other than could be expected to result from rest, an adequate diet, physical therapy and general measures of hygiene. In four of the patients (1, 3, 4 and 5) hemarthroses developed late in the course of ovarian treatment and in only one instance (case 5, chart 5) was there any demonstrable infection that might be

Chart 5—Observations on the complete coagulation time of the venous blood in cases 1, 5 and 6 during and after the oral administration of ovarian substance

considered a precipitating factor. In no instance could we obtain a history of unusual trauma, which might have caused these hemarthroses.

SUMMARY

The coagulation time of the blood of seven patients with hemophilia was observed repeatedly during treatment with ovarian substance or estrogenic substance. Large amounts of one or another of eight different preparations were given over periods of from twenty-eight to eighty-one days. In no instance was the coagulation time of the venous blood found to be depressed as the result of such therapy. Theelin (estrogenic substance) administered subcutaneously to two patients for from three to seven days neither stopped bleeding nor reduced the clotting time.

Estrogenic substance was demonstrated consistently in the urines of our patients both under ovarian therapy and during control periods. No correlation could be established between the quantity of estrogenic substance excreted in the urine and the fluctuations of the blood coagulation time.

No clinical improvement was noted which could be attributed to ovarian therapy. In four of the patients hemarthroses developed without obvious trauma or infection late in the course of treatment.

BLOOD GROUPS AND THERAPEUTIC MALARIA

SILIK H. POLAYES, M.D.

AND

IRVING M. DERBY, M.D.

BROOKLYN

Since malarial therapy for syphilis of the central nervous system has come into vogue, several problems of practical importance have arisen which have interested the physician employing this mode of therapy. For therapeutic as well as for economic reasons, it is highly desirable that the course of malarial treatment be as short as possible. Usually such a course, if successfully carried out, consumes from eight to ten days, with an incubation period of four days or less. Wide variations in the incubation period, however, have often prolonged the course of treatment, making it unsatisfactory from an economic point of view. In fact, frequently the patient has to be kept in the hospital for weeks because the malarial fever cannot be induced in spite of repeated injections of blood containing virulent parasites. This has been ascribed to the following causes: individual factors,¹ the manner of inoculation, i. e., subcutaneously or intravenously,^{2a} the stage of development of the parasite in the donor's blood,² the amount of blood injected,³ the strain of the organism, the temperature of the environment,⁴ and the compatibility between the donor's red blood cells and the recipient's serum. In 1927, Wendtberger,⁵ from a study of the blood groups of donors and recipients in fifty cases in which malarial therapy was used, found that in some instances in which the donor's cells were incompatible with the recipient's serum malarial fever could not be induced at all, while in others it was induced only after a prolonged incubation time. The success or failure in the attempt to induce malaria in these cases was found to depend on the agglutinin titer of the recipient's serum.⁶ Following Wendtberger's work, a number of similar investigations were carried out by Wethmar,⁷ Pilcz,⁸ Arzt and Fuhs,⁹ Herrmann and Hlshnikowski,¹⁰ and Walter.¹¹ With the exception of Walter's studies, the observations of Wendtberger have been almost unanimously confirmed.

An interesting phenomenon that has come to light in the therapeutic application of induced malaria, which

was first described by Korteweg¹² and later by Wethmar,¹³ is that of so called primary fever. This is a remittent fever without chills appearing about the fourth day after inoculation of the malarial blood and lasting until one or two days before or merging with the actual malarial chills. Although previously unrecognized as such, primary fever is now believed by some to occur in naturally acquired as well as in artificially induced malaria.¹⁴ Wethmar¹⁴ has shown that in induced malaria the occurrence and course of the fever are greatly influenced by the blood group of the donor and of the recipient. Thus he found that when the incubation time was short primary fever occurred in 100 per cent of the cases and lasted on an average of 3.7 days, while in the cases in which the incubation time was prolonged only 42 per cent presented primary fever, with an average duration of only slightly more than one day. Since the incubation time is influenced by the compatibility between the donor's cells and the recipient's serum it follows that the blood groups indirectly affect the frequency of occurrence and duration of the primary fever as well.

The importance of this phenomenon resides in the fact that patients who are too weak to be subjected to a high primary fever may be spared this additional strain by receiving incompatible malarial blood, which would greatly lessen the intensity as well as the possibility of the occurrence of primary fever.

Still another practical problem that has arisen as a result of the widespread use of malarial therapy is the possible danger of emboli, which might result from the injection of incompatible blood. It is conceivable in fact probable, that incompatible donor's cells, small though the quantity may be, might be agglutinated by the recipient's serum and result in emboli, which may produce infarcts in the lungs. In the presence of a patent foramen ovale this may even result in cerebral embolism. Wendtberger, Wethmar and others have recognized a definite reaction that follows the injection of incompatible malarial blood. This appears soon after the injection and consists of a rise in temperature with chills, nausea and dyspnea. It is significant that these reactions have been observed mainly in cases in which the incompatible blood was injected intravenously.

The American literature, with the exception of a study of twelve cases reported by Knights in 1930, has no information on any of these problems. However, since these problems appeared to be of sufficient importance to warrant further investigation, the present study was undertaken.

One hundred and twenty-seven cases of dementia paralytica were observed. Each patient received 5 cc of malarial blood intravenously a few minutes after the blood was withdrawn from the donor. The blood groups of donor and recipient were determined according to the method described by Landsteiner.¹⁵ From the time the patient received the blood the clinical course was carefully observed with regard to the following: (A) incubation period, (B) immediate or delayed incompatibility reactions (rise in temperature, embolic phenomena, dyspnea, gastric distress, chill, sup-

pression of urine, hematuria and the like) and (C) occurrence and duration of primary fever.

A Incubation Period—The data can be studied best from the accompanying table and chart. In the table the cases have been classified into two groups, namely, those receiving compatible and those receiving incompatible blood, with a record of the incubation period in each. It will be observed that in the former group¹⁶ the average incubation period is 4.30 days, while in the latter it is 8.18 days. That the difference between the average incubation periods of the two groups is not merely apparent but actually significant has been proved mathematically by Dr. A. S. Wiener.¹⁷ The accompanying chart is plotted from the figures in the table and shows more vividly the influence of blood compatibility on the incubation period.

A study of the table further discloses that in addition to the difference in the incubation periods noted in the two groups there is also a wide variation of the incubation period within each group, as evidenced by the large standard deviation. (The standard deviation was calculated to be 3.04 ± 0.24 days in the series receiving

compatible blood and 4.76 ± 0.51 days in the series receiving incompatible blood. This variation may be attributed to other factors already enumerated which influence the incubation period. One of the most important of these is individual resistance to malarial infection. Thus O'Leary and Welsh,¹⁸ in a recent report on a study of malarial therapy in 984 cases of neurosyphilis, found it impossible to induce chills and fever in 10 per cent of the patients inoculated, because of their immunity to malaria. In our series there were

16 This group could be subdivided into two groups, namely those receiving homologous blood (O → O, A → A, B → B and AB → AB) and those receiving heterologous blood (such as O → A, O → B, O → AB, A → AB, B → AB). In the former subgroup (forty-six cases) the mean incubation period was 4.64 days and in the latter (thirty-three cases) 3.85 days, so that there was no significant difference between the two types of cases. This is rather to be expected since it is the donor's erythrocytes and not the serum which contain the malarial parasite.

17 That the difference between the means of the two groups is significant may be proved by calculating the probable error of this difference. The probable error of a mean is given by the formula $P.E. = \frac{\sigma}{\sqrt{N}}$.

18 In which σ represents the standard deviation of the data and N the number of individuals examined. In the group receiving compatible blood, the probable error is 0.22 day, and in the group receiving incompatible blood 0.48 day. The probable error of the difference between the means is equal to $\sqrt{0.22^2 + 0.48^2} = 0.52$ day. Therefore the difference between the two means is more than seven times as great as its probable error. Since a difference of such a magnitude could occur by chance only in more than 1,000,000 trials it is unquestionably significant.

six cases (three in each group) in which malaria could not be induced, in spite of repeated inoculations with malarial blood. These failures were also probably due to the individual resistance to the parasite. It may be added that these cases were not included in the calculations in order to avoid masking the effect of the use of compatible and incompatible bloods.

B "Incompatibility" Reactions—Untoward reactions consisting of the symptoms already described occurred in eleven cases following inoculation of the malarial blood. In no instance, however, could it be determined with any degree of certainty that these reactions were

during the incubation period was frequently too irregular to conform rigidly to the definition of primary fever as stated by its authors.

SUMMARY AND CONCLUSIONS

A series of 127 cases of dementia paralytica treated with malarial blood was studied in order to determine (a) the effect of the injection of compatible or incompatible blood on the incubation period, (b) the occurrence of immediate or delayed reactions to incompatible malarial blood, and (c) the frequency of occurrence of so-called primary fever. The following conclusions may be drawn:

1 The average incubation period is 4.30 days when the malarial blood injected is compatible and 8.18 days when it is incompatible with the recipient's serum. That this difference is significant was proved by statistical analysis.

Wide variations of the incubation periods were noted in the group of patients receiving compatible as well as in those receiving incompatible blood. These differences may be ascribed to factors other than compatibility or incompatibility of blood.

2 With regard to untoward postinoculation reactions, it was not possible to determine with any degree of certainty that they were due to incompatibility between the donor's and the recipient's blood. Other possible factors may be responsible for these reactions.

3 Primary fever occurred in only 15 per cent of the patients receiving compatible malarial blood. These figures are much smaller than those found by previous investigators. The difference is perhaps due to the fact that it is difficult to recognize this phenomenon because the postinoculation temperature curve is frequently too irregular to conform rigidly to the definition of primary fever.

NECESSITY FOR REVISING THE COMMON CONCEPTION OF FOCAL INFECTION

MYER SOLIS-COHEN, M.D.
PHILADELPHIA

A focus of infection has been defined as a circumscribed area of tissue infected with pathogenic organisms.¹ General recognition that it can cause systemic or general disease makes its elimination an important part of the treatment of such disease.

COMMON MISCONCEPTION OF FOCAL INFECTION

In the common conception of focal infection, attention seems to be concentrated on the infected tissue rather than on the infecting bacteria. When a physician speaks of eliminating the focus of infection, what he really means is the removal of infected tissue such as tonsils and teeth or the opening and draining, or the cleaning out of an infected cavity, such as a nasal accessory sinus. He apparently fails to realize that, in the upper air passages, at least, infecting bacteria seldom are confined to a circumscribed area of diseased tissue but are present also on adjacent tissues. The germs infecting the tonsil, for instance, may be found on the adjacent mucous membrane of the throat and

Influence of blood compatibility on incubation period of infection malaria

due to incompatibility between the donor's and the recipient's blood. The donor's and the recipient's blood were compatible in the five instances in which chills and rise in temperature followed within one or two hours after inoculation. One of the severest of these reactions occurred in a case in which both donor and recipient belonged to group A (the subgroup was not determined). In seven cases, hemoglobinuria or hematuria followed the inoculation, but in four of these instances the bloods of donor and of recipient were compatible. Hence the observations of Wendtberger, Wethmar and others regarding blood incompatibility reactions were not confirmed in this study. It is possible that the various other factors that are known to produce untoward symptoms following intravenous injection of blood might have caused the reactions noted by the previous authors as well as by us. Among these causes may be mentioned foreign proteins (in the malarial cells as well as in the blood of the donor), incipient coagulative changes, and chemical contamination of the donor's blood.¹⁸

C Primary Fever—We have found it quite difficult to determine with certainty the occurrence of primary fever. The temperature curves after inoculation (during the period of incubation) in most cases failed to correspond with those described by Wethmar and the others who have described the phenomenon. In the group of forty-two patients receiving incompatible blood, primary fever developed in only five (or about 12 per cent) while in the group of seventy-nine patients receiving compatible blood, it developed in twelve (15 per cent). These figures are strikingly smaller than those given by Wethmar. The difference may be due to our failure to recognize the phenomenon. In our cases it was found that the temperature curve

nasopharynx and in the infratonsillar lymphoid tissue. Similarly the microorganisms infecting a sinus find their way to the nasal and nasopharyngeal mucous membrane. These microbes are not removed by tonsillectomy and simple treatment or operation but continue to live and multiply elaborating toxins and infecting distant tissues.

FOCUS OF INFECTION IN TONSILS NOT ERADICATED BY TONSILLECTOMY

Why should so many physicians, including otolaryngologists, state that the focus of infection has been eradicated after tonsillectomy? It is known that the surgeon frequently fails to remove all the tonsillar tissue leaving behind tonsillar stumps,² which constitute as great a focus of infection as did the whole tonsil. Indeed Rhoads and Dick³ believe that in many instances the condition resulting from incomplete tonsillectomy is worse than that existing before the operation. Even when a perfect tonsillectomy has been performed it often is followed by a recurrence of tonsillar tissue which may be just as serious a focus of infection as the original tonsil.⁴ The lymphoid masses commonly spoken of as recurrent tonsils⁴ but really nothing more than infratonsillar lymphoid tissue that has worked its way upward into the empty tonsillar fossa⁵ are regarded by French⁴ as quite as potent a factor of systemic infection as infected faucial tonsils, the same microorganisms being recovered from the two. Normal appearing tonsillar fossae also may harbor infecting organisms as I have repeatedly demonstrated⁶ and thus act as foci of infection. I made seventy-four pathogen-selective cultures of apparently clear tonsillar fossae and found infecting bacteria in seventy-three (97 per cent).

FOCAL INFECTION IN THE NASOPHARYNX NOT REMOVED BY OPERATION

When adenoid vegetations in the nasopharynx constitute the focus of infection adenoidectomy is supposed to eradicate it. Yet tags and remnants after adenoidectomy by skilled physicians were found by Hill⁷ in 25 per cent of 409 students over 16 years of age and in 50 per cent of 186 younger children.

The apparently normal nasopharynx frequently becomes the habitat of infecting germs and thus serves as a focus of infection, as I pointed out some years ago.⁸ I made 147 pathogen-selective cultures of the nasopharynx in suspected infections of the upper respiratory tract and found infecting organisms in 140 (95 per cent).

Frequently the same infecting bacteria that are present in diseased tonsils are living also in the nasopharynx. I made seventy-eight simultaneous pathogen-selective cultures of diseased tonsils and the nasopharynx, finding the same infecting organism in both cultures in forty-two (54 per cent). The nasopharynx on the other hand may contain infecting bacteria that are not present in the tonsils. In eighteen of the seventy-eight cultures (23 per cent) none of the infecting organisms present in the nasopharynx were found in the tonsils. Similarly the tonsils may contain infecting germs that are absent from the nasopharynx. In eighteen (23 per cent) of the cultures the tonsils contained infecting organism not present in the nasopharynx. The nasopharynx may also contain the same infecting organisms that are present in the tonsillar fossae, as occurred in thirty-eight (47 per cent) of eighty-one pathogen-selective cultures which I made simultaneously of each of these areas. In twenty-one (26 per cent) of these cultures no infecting microbe present in the tonsillar fossae was found in the rhinopharynx while in twenty-two (27 per cent) no infecting organism present in the nasopharynx was found in the tonsillar spaces. It has been my practice in recent years when searching for foci of infection, to make pathogen-selective cultures in the same tube of the tonsillar spaces and nasopharynx. I made 305 such cultures in 283 (93 per cent) of which infecting organisms grew up.

FOCI OF INFECTION IN NASAL ACCESSORY SINUSES NOT ELIMINATED BY TREATMENT OR OPERATION

A similar situation exists in regard to infection in the nasal accessory sinuses. When the rhinologist has opened and drained a sinus or has done a conservative or radical operation on it, he believes and reports that he has eradicated the focus of infection. The infecting organisms, however, frequently still remain in or about the treated sinus. I made 230 pathogen-selective cultures of the nares and thirty-five such cultures of the sinuses of patients who had received expert treatment for sinusitis and found infecting organisms in 180 (78 per cent) of the nasal cultures and in twenty (57 per cent) of the sinus cultures. Seventy-five simultaneous pathogen-selective cultures of the nares and the nasopharynx showed the same infecting germ in thirty (40 per cent). In twenty-one (28 per cent) none of the infecting germs present in the nares were found in the nasopharynx and in twenty-four (32 per cent) no infecting organism present in the nasopharynx was found in the nares. Nine simultaneous pathogen-selective cultures were made of the sinuses and the nasopharynx in one third of which the same infecting organisms were found in the two areas in another third the infecting organisms in the sinuses were absent from the nasopharynx, and in one third none of the infecting germs in the nasopharynx were found in the sinuses.

But not only is the rhinologist unable to eliminate a bacterial focus of infection in the sinuses, frequently

8 Solis Cohen Myer. The Rhinopharynx as a Site of Focal Infection. *Ann Otol Rhin & Laryng* 33: 935-950 (Sept.) 1924.

according to Skillern,⁹ Proetz,¹⁰ Carter¹¹ and Pond,¹² he fails to cure the sinusitis

FOCAL INFECTION IN THE ORAL CAVITY NOT
ALWAYS REMOVED BY THE EXODONTIST

Focal infection in the oral cavity as a rule can be eradicated by surgery, but it is not always removed when infected teeth are extracted. According to Post,¹³ a residual pathologic condition is a most important and often overlooked source of focal infection

SHOULD THE EXPRESSION "ELIMINATION OF THE
FOCUS OF INFECTION" BE APPLIED TO
MERE REMOVAL OF INFECTED
TISSUE?

In the interest of accuracy should not such expressions as "removal" or "elimination" or "eradication" of the focus of infection be avoided when tonsillectomy or sinus treatment or operation is being described? The physician then would not be influenced by this incorrect and misleading information to abandon his investigation of the upper air passages and in his search elsewhere for the elusive focus even to order sometimes the unnecessary extraction of healthy and useful teeth on the chance that the focus of infection might be there. Realization that the focus of infection had not really been eliminated might minimize his disappointment when no improvement in the systemic disease follows the operative procedure. A result helpful to science would be a lessening of the skepticism as to the etiologic importance of focal infection and of the tendency to assign a greater rôle to factors that may be unimportant or only of secondary significance

A REVISED CONCEPTION OF FOCAL INFECTION

If the conception of focal infection stressed the bacterial element and regarded the causal germ as the chief infecting agent, the problems involved in its eradication would be better appreciated. It then would not be so difficult, in the absence of recognizably diseased tissue, to conceive of a bacterial focus of infection, produced solely by infecting organisms living on an apparently normal mucous membrane where they multiply and elaborate their toxins. One would realize that surgery alone cannot possibly remove all the infecting organisms, which can be overcome only by the patient's defensive forces

MEASURES REQUIRED FOR ELIMINATING
FOCAL INFECTION

The elimination of a focus of infection requires the production of bactericidins and other antibodies to destroy the infecting bacteria and render their toxins harmless. In most cases it will be necessary at one or more foci to extirpate accessible and removable diseased tissue that has become a favorable soil for the growth of the infecting germs. Sometimes following such removal a patient regains his lost or lowered resistance and recovers from the systemic disease without further medical assistance. Such a striking cure following operation strongly impresses the physician, despite bitter disappointments in other cases, and

doubtless has helped to preserve the oft wavering belief in the focal origin of disease. It probably is one reason for the impression that the surgeon can remove a focus of infection. In my experience, however, such favorable results are not the rule.

In most cases the physician must come to nature's aid. Billings¹⁴ recognized this when he recommended not only removal of all primary and, if necessary, all secondary foci of infection but also the building up of the natural defenses of the body.

Before making a diagnosis of focal infection, however, one of course must be certain that the condition is not one of allergy, lack of proper vitamins or endocrine dysfunction.

Among the patients whose condition has been unaffected by operative procedures, a number will improve when their resistance has been raised by hygienic measures. Others will require, in addition, artificial stimulation of specific antibody production by means of vaccine, which must contain the proper specific antigens obtained from the infecting bacteria.

DETERMINING THE INFECTING BACTERIA

The chief objection to vaccine therapy in systemic disease is the difficulty or even impossibility of deter-

mining what germ is the cause of the disease and which, if any, of the bacteria at a supposed primary focus is the etiologic factor.

In a subacute or chronic infection the mere presence of microbes on or in infected tissue or in the secretion or excretion from it is no indication of any etiologic relationship between them and that infection. Indeed, such germs may not even be pathogenic for the patient, as I have repeatedly shown. Yet many autogenous vaccines are made up from just such organisms. Nor is the predominating germ necessarily the causal one in subacute and chronic infections, although many physicians and even some bacteriologists make their vaccine chiefly from it. Of 384 cultures made in Rosenow's brain broth, the predominating organism was capable of infecting the host in only 215 (56 per cent) and was nonpathogenic in 169 (44 per cent). The accompanying table shows the percentages for the different organisms. Moreover, in over 10 per cent of all the cultures in Rosenow's brain broth the infecting organisms failed to grow up.¹⁵ This I have attributed to their being

overgrown by the more numerous organisms that are nonpathogenic to the patient¹⁶. Is it to be wondered if therefore that vaccines so prepared often have little or no therapeutic effect?

For determining the causal organism in a subacute or chronic infection a number of methods have been devised utilizing improved technique, differentiating mediums, animal passage, the bactericidal power of whole blood tests for hypersensitiveness and serologic tests, including agglutination, precipitation, hemolysis, absorption, complement fixation tests and the like. The pathogen-selective method is based on the assumption that organisms capable of growing in the fresh, whole, coagulable blood of the patient are those which are most pathogenic for that individual.¹⁷ One of its advantages is that it furnishes a means for selecting the etiologically important organisms from a mixed culture. It is the only selective method described in Kolmer and Boerner's *Approved Laboratory Technique*¹⁸. Its simplicity makes it easily available for clinical use.

ERADICATING THE BACTERIAL FOCUS OF INFECTION BY MEANS OF VACCINE

In order to eradicate a bacterial focus of infection by stimulating resistance to the infecting bacteria and their toxins the vaccine must contain all the infecting organisms. This necessitates taking proper cultures of all possible foci, including the nasopharynx, which, as has been shown, may contain infecting organisms not present in the tonsils or in the tonsillar fossae. The vaccine in my opinion should contain as many antigens as possible, the soluble exotoxins as well as the endotoxins. Such a vaccine, however, is extremely potent and must be employed with great caution.

When the required specific antibodies have been produced in sufficient quantities to overcome the infecting organisms and their toxins, the focus of infection can truly be said to be eradicated at both the primary and the secondary foci.

CONCLUSIONS

1 The common conception of focal infection concentrates attention on the infected tissue rather than on the infecting bacteria.

2 When the physician speaks of eradicating a focus of infection, what he really means is removing infected tissue, such as tonsils or teeth, or draining and cleaning out an infected cavity, such as a nasal accessory sinus.

3 Infecting bacteria seldom are confined to a circumscribed area of diseased tissue but are present also on adjacent tissues, which may be apparently free from disease.

4 Enucleation of diseased tonsils does not necessarily remove the focus of infection, because the infecting organisms may still remain in tonsillar stumps, in recurring tonsillar tissue, in infratonsillar lymphoid tissue, and on the apparently normal mucous membrane of the tonsillar fossae and the nasopharynx.

5 A focus of infection in a nasal accessory sinus is not necessarily eliminated by treatment or operation, because infecting bacteria may still persist there.

6 Such expressions as "removal" or "elimination" or "eradication" of the focus of infection should be

avoided when one is describing tonsillectomy or sinus treatment or operation.

7 The conception of focal infection should stress the bacterial element and regard the causal germ as the chief infecting agent.

8 Surgery alone cannot possibly remove all the infecting organisms, which can be overcome only by the patient's defensive forces.

9 The elimination of a focus of infection requires the production of bactericidins and other antibodies to destroy the infecting bacteria and render their toxins harmless, which can be aided by hygienic measures but in many cases needs the artificial stimulation of a potent vaccine containing the proper antigens obtained from the infecting bacteria.

10 The pathogen-selective culture selects the etiologically important organism from a mixed culture, and the vaccine made from it contains both the endotoxins and the soluble exotoxins of the infecting bacteria.

11 When, in addition to the extirpation of accessible and removable diseased tissue that has become a favorable soil for the propagation of the infecting germs, the required specific antibodies have been produced in sufficient quantities to overcome the infecting organisms and their toxins, the focus of infection can truly be said to be eradicated at both the primary and the secondary foci.

EFFECT OF DIATHERMY TREATMENT OF KIDNEYS ON THE RENAL FUNCTION

AS MEASURED BY THE UREA CLEARANCE TEST

IRVINE H. PAGE, M.D.

NEW YORK

Largely as the result of the speculation that Bright's disease results from spasm of the renal vessels, diathermy treatment has been extensively employed in this disease in the past few years. The belief has prevailed that the diathermy current actually heats the kidney and thus causes relaxation of the arteriolar spasm, in turn resulting in better perfusion of the kidney with blood.

Contradictory literature has grown up regarding the observed effects of renal diathermy.¹ Some investigators have found neither a diuretic effect nor any evident therapeutic advantage, whereas others have stated that they have had good results.

In order to obtain evidence concerning the effects of diathermy on renal function I have observed the effect of one-hour periods of diathermy on the urea clearance. The subjects were either normal or those suffering from hemorrhagic Bright's disease, nephrosis, or essential hypertension.

PROCEDURE

The patients were all kept in bed during the test. A control period of one hour was run followed by one

ance was estimated as described by Møller, McIntosh and Van Slyke.

The diathermy machine employed was number 4 of the Westinghouse X-Ray Company. One electrode was placed over each kidney region and a large electrode over the upper part of the abdomen. An attempt was made to give as high dosage as could be tolerated by the patient without serious discomfort. In most cases from 1,700 to 1,900 milliamperes could be employed.

RESULTS

The accompanying table presents the results of the diathermy treatment.

In all cases the blood urea was not changed to any large extent there being a slight tendency to fall from the first period to the last. Also, no consistent change in the water excretion was noted, and, lastly, the urea clearance was not altered significantly. Blood pressure measurements during the diathermy treatment showed no consistent change from the control level.

SUMMARY

Diathermy treatment has been given to fourteen subjects (normal subjects and patients with hemorrhagic Bright's disease, nephrosis and essential hypertension) for one-hour periods. No significant change was observed in the blood pressure or in the renal function as measured by the urea clearance test, diuresis or blood urea. The results afford no support for the assumption that renal diathermy is of therapeutic value in essential hypertension or Bright's disease.

CREATINE METABOLISM IN CHILDREN WITH HYPOTHYROIDISM

HENRY G. PONCHER, M.D.
MAURICE B. VISSCHER, PH.D., M.D.
AND
HELEN WOODWARD, M.S.
CHICAGO

The discovery of metabolic functions of creatine in muscle metabolism has attracted considerable clinical interest in the study and treatment of disorders of the muscular system particularly in pseudohypertrophic muscular dystrophy and myasthenia gravis. This subject was reviewed by Harris and Brand¹ in a recent issue of THE JOURNAL.

Evidence is gradually accumulating, however, which indicates that the metabolism of creatine has a wider clinical importance than in the specific myopathic diseases. Changes in creatine excretion have been noted in individuals not suffering from disorders of the muscular system. A detailed discussion of these changes and their significance in the various phases of normal and pathologic physiology may be found in the writings of Hunter² and Rose.³ It seems likely that creatinuria in the human being is related to defective creatine storage in muscle or to abnormally high creatine synthesis. Creatinuria occurs in all types of muscular dystrophy and in states of increased endogenous protein catabolism, as in fever and in certain cases of

* Corrected urine volume is the observed urine volume x 1.79 sq meters body surface. The correction is used as described by McIntosh and Van Slyke.

hour of diathermy and again a one-hour control period. Four hundred cubic centimeters of water was given just before the collection of the first urine specimen and again before the diathermy was started. The blood urea was determined in the middle of each period. Before, during and after the diathermy the urea clear-

hyperthyroidism. Apparently a number of factors play a part in determining the extent of normal creatinuria, which in the present state of knowledge cannot be definitely interpreted.

Normally creatine is not found in the urine of the male adult but small amounts of creatine are excreted periodically in the urine of normal women, possibly indicating a controlling influence of the sex hormones.⁴ In infants and children, however, creatinuria is physiologic in both sexes until about the age of puberty. This fact was first pointed out by Rose⁵ in 1911. Almost simultaneously McCrudden⁶ published the results of his investigations on the effect of carbohydrate and fat on the excretion of creatine in cases of retarded development. One of his subjects was a female cretin aged 8 years in whom creatine excretion was markedly reduced. The significance of this observation was not appreciated at the time as there were meager data on creatine metabolism in pathologic conditions. However some years later Beumer and Iseke⁷ observed that hypothyroidism in children was invariably accompanied by a diminution and sometimes by a complete suppression of creatine excretion.⁶ The same investigators also demonstrated that the creatine excretion in hypothyroid children returns to normal after the administration of thyroid extract. Since this observation other investigators have noted an apparent relationship of creatine metabolism and thyroid activity.⁸ Experimentally, it has been shown that operative removal of the thyroid gland leads to a reduction or complete cessation of creatine excretion and that it promptly returns to normal after the giving of thyroid extract.¹⁰ It has also been shown that the thyrotropic hormone of the anterior pituitary lobe has almost the same effect as thyroid extract in producing an increased excretion of creatine in the normal adult rat.¹¹

From these observations it appeared that the relationship of the creatine metabolism to thyroid activity might be of clinical interest. A number of clinical observations have been made in adults with severe hyperthyroidism when an increased creatine excretion has been found.¹² This information has limited clinical application for purposes of diagnosis, as the finding is not altogether consistent and as there are other more reliable diagnostic aids in that condition. In children, however, hypothyroidism often presents a difficult problem for diagnosis and treatment, particularly in borderline cases.

It seemed advisable therefore, to investigate further the clinical significance of diminished thyroid activity and creatine metabolism during the period of childhood

PROCEDURE AND METHODS

Extensive creatine and creatinine excretion studies have been carried out on thirty-four children, normal and with various types of pathologic conditions. Detailed observations are reported at this time on two cases of hypothyroidism in children. Twenty-four hour urine specimens were collected on two girls with hypothyroidism, one (D J, aged 5 years) for fifty-three consecutive days and another (V K, aged 12 years) for thirty-six consecutive days. The preformed creatinine was determined by the Folin colorimetric method and by the total creatinine by the Folin-Benedict method in duplicate. The patients were on a general hospital diet containing meat once a day and approximately a quart of milk a day.¹³ Rectal temperatures were taken three times a day. As soon as the patients were stabilized metabolically, a creatine toler-

Chart 1—Observations in the case of D J, a girl aged 5 years

ance test was given consisting of 3 Gm of creatine by mouth daily for seven days (D J) and five days (V K). The amount of creatine fed and eliminated is given in the charts. The periods in which thyroid extract was administered are indicated as to time and dosage.

METABOLIC AND THERAPEUTIC OBSERVATIONS

The subjects showed an absence of the physiologic creatinuria of childhood when not receiving thyroid therapy or creatine by mouth. The absence of creatine from the urine was not due to a low protein intake, as the diet described was not creatine free and contained an adequate amount of protein. In the case of the older subject (V K), the experimental period was started while she was still on thyroid extract. This

13 The children were purposely not put on a weighed creatine free diet as it was desired to study the creatine excretion under natural clinical conditions.

patient showed a gradual decrease in urinary creatine as the amount of thyroid extract administered was reduced. She continued to excrete creatine for three days after thyroid therapy was discontinued. Another hypothyroid child under observation showed the same reaction.

Creatine appeared in the urine the day following thyroid administration and continued as long as the thyroid extract was given. A temporary increase in creatine excretion was noted immediately following an increase in the dose of thyroid extract. The thyroid therapy had no appreciable effect on the preformed creatinine excretion. The total creatinine coefficient of the younger patient (D J) without treatment averaged 21.2. On thyroid treatment the average rose to 29.0. The first figure is lower and the latter figure higher.

Chart 2—Observations in the case of V K, a girl aged 12 years

than the creatinine coefficient of 23, which is considered by Harding and Gaebler¹⁴ to be normal for children. The older subject (V K) had an average total creatinine coefficient of 15.4 without treatment. On thyroid treatment the coefficient rose to 24.6.

The fate of ingested creatine in these cases is of interest. The younger child (D J) excreted only 45 per cent of the ingested creatine as creatine and showed no increase in creatinine excretion. This subject continued to excrete creatine in considerable quantities for four days after ingested creatine was discontinued. The older child (V K) excreted only 19 per cent of the ingested creatine but showed a definite rise in creatinine excretion. This patient excreted a small amount of creatine the day after creatine feeding was stopped, but it completely disappeared from the urine after the second day.

COMMENT

The hypothyroid children studied have shown a definite change in creatine metabolism. This is characterized by a diminution or complete absence of the physiologic creatinuria usually found in children up to the age of puberty. Thyroid feeding restores the hypothyroid child to the condition of creatinuria characteristic of the normal child. The creatinuria is seen to be a very delicate index of the effect of ingested thyroid, as it occurs even before any definite change is noted in the basal metabolism and blood cholesterol. It is not possible to state how the thyroid hormone affects the creatine metabolism, but it is obvious that directly or indirectly it exerts a profound and determining influence on the character of creatine metabolism. A probable explanation of the diminished creatine excretion is that it may be due to a low endogenous metabolism incident to hypothyroidism.

The response of the subjects to ingested creatine is also interesting. Both children have a greater tolerance for creatine than normal children of the same age. Krause¹⁵ fed a considerably smaller quantity of creatine to two normal girls, one, aged 6 years, excreting creatine, and the other, aged 11 years, not excreting creatine. He found 56 per cent of the ingested creatine excreted in the case of the younger child and 31 per cent in the case of the older child.

Magee¹⁶ studied two normal boys, aged 6 and 9 years, and found, respectively, 75 and 33 per cent of the endogenous creatine excreted as such. She also noted less conversion to creatinine and a more prolonged creatine excretion over a longer period of time in the younger child.

It has been found that with normal subjects the younger the child the relatively greater amount of both endogenous and exogenous creatine is excreted. In the two subjects studied there was an absence of endogenous creatine excretion during the period in which they were not receiving thyroid. When creatine was fed by mouth during the control period, the tolerance for creatine was found to be greater than in normal children and less appeared in the urine. Moreover, the normal tendency of the younger child to excrete more creatine on a creatine tolerance test is seen to be exhibited under conditions of hypothyroidism. In other words, while the quantitative response to the creatine tolerance test is modified by the condition of hypothyroidism, it has not altered the influence of age. The factors inherent in the age of the patient require further study.

The comparison of the changes in creatine excretion with other criteria of the efficacy of treatment in hypothyroidism is interesting. It will be noted from the charts that following thyroid therapy a change in creatine excretion takes place long before there is a significant change in the basal metabolic rate, blood cholesterol or body weight. From these observations it seems apparent that measurement of the urinary creatine is a delicate index of the effect of thyroid administration. In view of the greater ease, simplicity and reliability of creatine analysis than of the basal metabolic rate in children, it seems that this measurement may serve as a useful clinical aid in controlling thyroid medication.

SUMMARY AND CONCLUSIONS

- 1 The metabolism of creatine appears to be definitely influenced by thyroid activity during childhood.
- 2 During the period from infancy until about puberty creatinuria is physiologic. Hypofunction of the thyroid causes a decrease or complete cessation of creatine excretion which can be restored to normal values after the administration of thyroid extract. This is accompanied by a corresponding change in the clinical condition of the patient.
- 3 From a comparison with other diagnostic criteria of hypothyroidism in children the change in creatine metabolism appears to be an important finding which may be useful in diagnosis and in the control of therapy.

ENDEMIC TYPHUS FEVER IN HAWAII

LERIC A. FENNELL, MD

HONOLULU, HAWAII

There is an ever increasing interest in the epidemiology and geographic distribution of American typhus fever.

Epidemic (Old World) typhus fever was well known to the physicians of the early nineteenth century. Typhus fever was first differentiated from typhoid by Gerhard, studying the Philadelphia epidemic of 1836. Typhoid means a disease like typhus fever. Typhus abdominalis became a clinical entity under the name of typhoid.

Eberth in 1880 and Gaffky in 1884 discovered the typhoid bacillus, now more properly designated *Eberthella typhi*.

Brill in 1897 observed a disease in New York which he differentiated from typhoid and which for a long time, bore his name. At that time he considered it a distinct clinical entity in no way related to typhoid, nor, later, to typhus fever. Subsequently it was proved to be immunologically similar to European typhus.

In 1906 Ricketts discovered the small gram-negative intracellular bodies that bear his name "*Rickettsia*" in the wood tick that transmits Rocky Mountain spotted fever, and these were later found in the human subjects of the disease, as well as in typhus fever subjects and typhus fever lice.

In 1909 Nicolle first succeeded in infecting monkeys with blood from typhus fever patients. Later it was demonstrated that in guinea-pigs the disease has a unique course.

In 1910 Wilson of Belfast and in 1914 Weil and Felix discovered that certain strains of *B. proteus-vulgaris*, isolated from the urine of typhus fever patients were agglutinated in high dilution of blood from typhus fever patients. This is a heterologous agglutination, since the agglutinable strain of *B. proteus-vulgaris*, known as *Proteus X 19* has no etiologic relationship to typhus fever. In low dilutions nonspecific agglutination may take place, but in dilutions over 1:300 it points quite diagnostically to typhus fever or Rocky Mountain spotted fever. This reaction, known as the Weil-Felix reaction, may become positive as early as the fifth day of the disease.

In 1931 Dyer and his associates conclusively proved that typhus fever (American variety, alias Brill's disease) was carried by the fleas of wild rats.

Most of the foregoing facts had been lost sight of by Honolulu physicians for at irregular intervals during the past ten years, sporadic cases that clinically rather closely resembled typhoid have been reported as typhoid or paratyphoid in the face of consistently negative laboratory observations. Most of these cases were rather similar—a prodromal period rather sudden onset rose spots of exaggerated character on the chest abdomen inner arms and thighs (but not on the wrists ankles or face), headache, cough fever as high as 104 F., a spleen normal in size, no enteric symptoms save frequently constipation, sterile blood cultures stool cultures negative for the typhoid group (occasionally a bacillus suspected of being paratyphoid C)—afebrile a bit too early for typhoid, negative Widal reaction and negative agglutination reaction for *Alcaligenes abortus*, *Alcaligenes melitensis* and the bacillus of tularemia. The laboratories received undeserved criticism. The clinician and the clinical pathologist were making the same mistake again and again and calling it experience.

Almost a hundred years after Gerhard differentiated typhoid from epidemic typhus fever the physicians of Honolulu were faced with the need to differentiate endemic typhus fever from typhoid. McCoy of the National Institute of Public Health, here to investigate leprosy in August 1932, suggested that this atypical symptom complex might belong in the group of Rickettsia or typhus-like diseases. He was good enough to send us subcultures of *Proteus X 19*.

Not until recently did an opportunity to investigate a typical case present itself.

Mrs. S. became suddenly ill with headache, malaise and body pains Sept. 2, 1933. September 23 she was again afebrile and convalescent. During the three weeks of her illness she presented the characteristic manifestations of headache, malaise constipation and later loose bowels, "typically exaggerated maculopapular rose spots," no splenic enlargement fever to 104 F., negative blood and oft repeated feces cultures, and negative agglutination reactions, even after convalescence, with *B. typhosus*, paratyphoid A and B, and *Alcaligenes abortus*, *Alcaligenes melitensis* and the bacillus of tularemia. There were no complications nor sequelae.

October 9 the blood serum, in a dilution as high as 1:10,000 gave an easily read agglutination of *Proteus X 19*, a twenty-four hour culture being used, suspended in saline solution and incubated two hours at 37 C. and in the icebox over night. Control serums did not agglutinate in dilutions of 1:320, though some were positive in 1:160. This seemed to offer conclusive proof that the patient had been suffering from endemic typhus fever since the symptomatology ruled out epidemic typhus fever as well as Rocky Mountain spotted fever, both of the Western and Eastern type.

Just previous to the inception of her illness the patient had moved into a newly constructed house the yard of which had served as a trash dump for neighbors during the construction, affording an excellent rat harborage.

I investigated with the Weil-Felix reaction a series of patients sick two years previously. In the H family of three the father had first become ill with the symptoms of an atypical typhoid. The father had hardly entered convalescence when the young son contracted the same disease. Shortly after that the mother became ill with the same symptoms, excepting that in her case the rose-macular rash was very prominent. All three patients made rather rapid recoveries. Two years after the illness the serum of the father agglutinated *Proteus X 19* in a dilution of 1:320 the son's in 1:640 and the mother's in 1:1,280. At the time of their illness many laboratory procedures had been instituted in their cases as well as in the case of a maid suspected of being a typhoid carrier in an effort to confirm the diagnosis of typhoid all to no avail. At the time of their illness this family had had in their home a small

colony of white rats, as pets, whose cage was accessible to wild rats. The female white rat was sick at that time and for that reason the colony was given away just after Mrs. H's illness.

A further survey showed that three other patients, leaving the hospital just recently with a diagnosis of fever of undetermined origin, gave strong Weil-Felix reactions, one in a dilution of 1:5,000, another in 1:10,000. Another patient, Miss M., ill at that time in the hospital with typical symptomatology, but admitted with a provisional diagnosis of typhoid or measles, on or about the seventeenth day of the disease gave a Weil-Felix reaction in a dilution of 1:80,000.

At the present writing about ten cases have been detected in Honolulu. These facts were presented before the Honolulu County Medical Society, Nov. 3, 1933, and it is anticipated that more cases will now come to light. Honolulu has recently been through a prolonged spell of very dry weather, excellent for the breeding of rat fleas, and the present high incidence of endemic typhus fever may be dependent on that fact.

Three cases of unconfirmed typhoid of from one to two years ago failed to give any agglutination with *Proteus* X 19, not all unconfirmed typhoid is necessarily typhus fever.

The older writings, in a confused fashion, tell of epidemics of typhus fever in the Sandwich Islands, certainly there has been no Old World typhus fever here since 1898. Just what the interepidemic reservoir of Old World typhus fever is seems to be still a mystery. This disease, transmitted from man to louse to man, might outlive the interepidemic period in man in an attenuated, afebrile form, but no proof of this has been advanced. The louse does not transmit the disease to the rat or to the next generation.

Endemic typhus fever is to be found chiefly on the Atlantic and Gulf seaboard, from the North, well into the South, and as far inland as Montgomery, Ala. A focus in and around Savannah, Ga., seems to have been closely studied, under observation, Dr. V. H. Bassett says its mortality is certainly increasing. While the mortality is usually given as 1 per cent, there has been one death for each twelve cases in the course of a certain year.

As far as I can determine, no cases have been reported from the inland part of the United States, from the Middle West or from the Far West. Cases have been reported from southern California and from several other points within the continental part of the United States, but there is reason to believe that these were imported cases of Mexican Tabardillo fever, more akin to Old World typhus fever in its mode of transmission and mortality. If, in the Middle and Far West, every case of fever of unconfirmed origin should be given the benefit of a Weil-Felix reaction in addition to the Widal, it is possible that new foci of the disease might be discovered.

While epidemic typhus fever is a disease of man, transmitted from man to man by the louse, endemic typhus fever is essentially a disease of rats transmitted to the flea and then, by accident, transmitted to man. Here the passage ceases, the quarantine regulations should be aimed at the rats, not the patient. It has been proved that rats from an area in which human cases of endemic typhus fever have arisen carry in their brains and suprarenals the virus of the disease.

Epidemic typhus fever is a disease of winter, endemic typhus fever one of summer and fall. The time of greatest prevalence of lice is winter, that of fleas is summer and fall. Fortunately, in the East, the prevalence periods of these two vectors do not much

overlap. Even in the southern part of the United States there are seasonal changes.

Here in Hawaii, however, temperature and seasonal fluctuations are practically nil, almost any month of the calendar may be the hottest, the coldest, the wettest or the driest. Of rat fleas there are plenty, fortunately there are not many lice, but they do exist. And now there is reason to believe that there is an endemic typhus fever reservoir in our rats. With this marked overlap of vector seasons, it will be interesting to see whether some day unwittingly the experiment of passing the virus of endemic typhus fever may be performed from a rat to a flea, and from that flea to a louse-infested man, and from that man to a louse, and from that louse to a second man. What will the second man have, endemic typhus fever or epidemic typhus fever?

On two of our islands, Hawaii and Maui, there exist limited areas in which the rat population is infected with plague bacillus and in which areas occasional human cases appear. There is at present being conducted through cooperation of the federal and territorial governments, an intensive epidemiologic survey of the rat and flea situation, from the plague point of view. This machinery, already set up might with little additional expense and labor investigate the same rats and fleas for the presence of endemic typhus fever. It is obvious that further cross protection experiments in guinea-pigs, with the viruses of typhus fever, epidemic and endemic, and spotted fever, Eastern and Western must be carried out against the local infection. The local material must come from human patients, rat fleas and rat tissues. At present the mentioned stock strains of viruses are not available in the territory.¹

The established presence of endemic typhus fever in Honolulu should be of considerable interest not only to the local health authorities but also to those of Seattle, San Francisco and Los Angeles, as well as to those of Japan, China and the Philippines. With the ever decreasing time of transport from one of these places to the other, the danger of disseminating this disease increases. While rat guards are placed about shipping with meticulous care, there is always danger of a break in technique. At present, with its three weeks of illness and a very low mortality rate, this disease has a greater economic importance than one of public health. But who is to say, with accuracy, what our peculiar geographic location plus our peculiar climatic conditions may mean to the natural history of this disease?

881 Young Street

¹ Since the foregoing was written serum from one of the reported cases was submitted to the U. S. Public Health Service and protection tests were carried out at the National Institute of Health through the courtesy of that bureau. Of six control pigs inoculated with typhus virus only all developed characteristic fever and serological lesions. All six pigs inoculated with this virus plus 0.5 cc. of convalescent serum failed to develop characteristic fevers and serological lesions. This makes the diagnosis of endemic typhus highly presumptive.

Ketosis—Under conditions of starvation or the administration of a diet low in carbohydrate and high in fat or in diabetes in which the carbohydrate metabolism is perverted, keto acids are produced in the body. These acids appear in the blood and are excreted into the urine by the kidneys as aceto-acetic acid and β -hydroxybutyric acid, the latter being produced apparently by reduction of the former. The acetone excreted is formed by the decomposition of these acids. This condition of ketosis arises from the failure of oxidation of the fatty acids with an even number of carbon atoms beyond the point where the chain is reduced to the four carbon acids above mentioned.—Gainsborough. *Hugh The Therapeutic Use of the Ketogenic Diet Practitioner* 132:45 (Jan) 1934.

SEVERE GRANULOPENIA FOLLOWING
THE USE OF BARBITURATES
AND AMIDOPYRINE

REPORT OF A CASE

CLAUDE L. RANDALL, MD
KANSAS CITY, MO

Following Schulz's classic description of agranulocytosis in 1922 reports of an apparently primary type of leukopenia have become increasingly numerous. According to the recent statement of Madison and Squier¹ over 500 of these cases are now on record. Wells² has quoted Stursherg, Marchand and Blumer as stating that differentiation during life between overwhelming suppurative so-called aleukemic leukemia and agranulocytosis may at times be impossible. With this in mind it would be helpful to call these cases granulopenia. Kracke³ has suggested this term because it places emphasis on the one common observation and accurately describes the characteristic blood picture. Obviously, much would be gained if these conditions could be classified according to the etiology involved.

It has long been recognized that benzene is highly toxic to the bone marrow, and benzene poisoning has been extensively studied both clinically and experimentally. It has only recently been suggested, however, that the enormous number of drugs containing a benzene chain might be a source of benzene intoxication. Emile-Weil⁴ recently pointed out that the incidence of benzene poisoning has been increasing parallel with the increasing use of benzene in industry. Likewise, it may be significant that the apparent increase in the incidence of granulocytic leukopenia parallels the increasing use of such benzene derivatives as the barbiturates and amidopyrine.

The following case is presented because it adds to the evidence suggesting that severe granulopenia may follow from the combined administration of such commonly used drugs as Luminal and Pyramidon.

REPORT OF CASE

A woman house physician, aged 25, had been previously in good health. Oct 31, 1933, because of headache, she took amidopyrine (Pyramidon), 5 grams (0.3 Gm.), and phenobarbital (Luminal), one half gram (0.03 Gm.), at 1 p m. During the afternoon she felt as though she was "coming down with a cold" and complained of continued headache, malaise and chilliness. Her temperature first taken at 5 p m was 101 and she went to bed at that time. At 7 p m she took allylisopropylbarbituric acid (Alurate) 2 grams (0.13 Gm.) and one tablet of Lumodrin the latter containing according to the label Ephedrin hydrochlorid gr $\frac{3}{8}$, Luminal, gr $\frac{1}{4}$, Pyramidon gr 2. At 8 p m she suffered a severe shaking chill and was moved into isolation quarters. Her fever at 10 p m was 103 and the pulse rate was 120. Physical examination was otherwise entirely negative. The next morning the laboratory found the hemoglobin to be 71 per cent the red cell count 3,820,000 and the white cell count 2,950, with 51 per cent of polymorphonuclear neutrophils. Three hours later the total white count was unchanged, but 10 per cent of immature neutrophils were noted. At 4 p m the white cell count was 2,050 with only 30 per cent of granulocytic cells,

17 per cent of which were myelocytes. During the next two days the total white count remained practically unchanged but the differential counts showed a slowly increasing percentage of mature granulocytes. Blood films were examined repeatedly for malarial but nothing suggestive was seen. The urine was normal. On the fourth day the white count was 2,900, with only 3 per cent of immature granulocytic cells. Except for continued weakness the patient felt practically normal. On the fifth day she returned to duty, feeling stronger but with a white count still under 4,000 and a differential count at times showing myelocytes and many band forms. Several days later, when the possibility was realized that the drugs used might have been responsible for the chill and leukopenia, the following additional interesting history was obtained.

The patient had been quite certain that she had not previously used either barbiturates or amidopyrine except on one other occasion, and that almost a year before. At that time, the onset of a week's illness had also been preceded by an afternoon headache. She had then likewise taken amidopyrine and phenobarbital for relief. A few hours later she had suffered a chill and afterward remained in bed several days on account of weakness. Her condition had at that time been regarded as a case of influenza, but no blood counts had been taken on that occasion.

It was practically six weeks before a normal differential count was recorded, when the total count was 7,000. Except immediately after the initial chill her temperature has been normal. This fact, together with absence of palpable glands or spleen and so uneventful and complete a clinical recovery, appears to rule out everything except a transitory leukopenia.

I have recently attempted to evaluate the allergic factor in this patient's reaction to phenobarbital and amidopyrine by injecting, subcutaneously, small amounts of each drug, both separately and combined, in saline solution. The local reactions were slight and seemed to indicate no hypersensitiveness to the benzene chain as far as the patient's skin was concerned. Likewise no appreciable change was noted in the leukocyte count following the injection of such small amounts of these drugs.

COMMENT

In 1931 Kracke⁵ reported severe and repeated attacks of agranulocytosis in an individual using large amounts of coal tar derivatives. At that time he suggested that the benzene chain contained in these drugs might act as a powerful leukocytic depressant. More recently he⁶ has reported that a review of nine cases of agranulocytosis revealed that eight of these individuals had been taking benzene derivatives prior to the clinical onset of their illness.

It is the commonly accepted belief that the reacting power of the individual's bone marrow determines the type and effectiveness of all leukocytic response. This fact serves to emphasize the seriousness of employing drugs that may be capable of depressing the mechanism of leukocytosis. It seems only a matter of wisdom in the light of recent observations, to regard the use of barbiturates and amidopyrine with this possibility in mind. Available evidence is hardly sufficient to contraindicate entirely the use of these drugs, but their administration calls for watchful supervision on the part of both the clinician and the laboratory.

SUMMARY

Granulopenia should not be regarded as a primary type of blood dyscrasia until all possible etiologic factors have been eliminated.

An apparent increase in the occurrence of granulopenia may be related to the widespread use of drugs containing a benzene derivative.

A woman, aged 25, developed an acute and alarming leukopenia following the use of barbiturates and amidopyrine for the relief of a simple headache.

From the Department of Pathology St. Luke's and Children's Mercy Hospitals.

Am. J. Clin. Path. 2: 11 (Jan.) 1932.

The benzene chain contained in both drugs is possibly responsible for the severe reaction and the disappearance of the granulocytes from the blood

A number of similar cases have been reported recently

A difference may be expected in the reaction to benzene quickly absorbed from the alimentary tract, as compared to the type of benzene poisoning that may result from the prolonged, slow absorption that occurs in industrial exposure

Individuals are known to vary greatly in their susceptibility to benzene. Granulopenia following the use of barbiturates and amidopyrine may therefore occur only in those individuals who are unusually susceptible to the benzene chain

CLINICAL MANIFESTATIONS OF HIGH AND LOW PLASMA MAGNESIUM

DANGERS OF EPSOM SALT PURGATION IN NEPHRITIS

ARTHUR D. HIRSCHFELDER, M.D.

WITH THE TECHNICAL ASSISTANCE OF

VICTOR G. HAURY, B.A.

MINNEAPOLIS

Although a great deal of clinical significance has been attached to variations in blood calcium, variations in blood magnesium have entirely escaped notice. Very little has been known even about what happens when a patient takes an ordinary purgative dose of epsom salt. Matthew Hay¹ found that one normal man excreted 28 per cent of the ingested magnesium through the kidneys in twenty-four hours, and Yvon² found 21 per cent. Using a new and convenient method for the quantitative determination of magnesium in blood plasma and urine, we³ have found that seven normal men excreted from 40 to 44 per cent (average 42.6 per cent) of the magnesium taken in a single ordinary purgative dose of epsom salt within twenty-four hours after ingestion. However, in spite of the large amount of magnesium absorbed, the concentration of magnesium in the blood plasma (normal, from 1.8 to 2.5 mg of magnesium per hundred cubic centimeters, average normal, 2.09) is scarcely affected (average increase, 0.24 mg of magnesium per hundred cubic centimeters, maximum increase, 0.41 mg). In normal dogs and normal rabbits the percentage of ingested magnesium that is excreted and the concentration of the magnesium in the blood plasma are almost exactly the same as in man, and with corresponding doses by mouth the plasma

concentration also remains practically unchanged. In animals the percentage of the ingested magnesium that is excreted in the urine is practically constant, regardless of the dose ingested or of the concentration of magnesium in the blood plasma.

HIGH PLASMA MAGNESIUM (HYPERMAGNESEMIA) AND EPSOM SALT PURGATION

However, when the kidneys are injured, the results are totally different. We have found in animals in which renal injury had been produced experimentally that less magnesium is excreted than normally. The excretion of magnesium is less in animals in which the tubules are more severely injured than the glomeruli (corrosive mercuric chloride nephrosis) than in those in which the glomeruli are injured more than the tubules (cantharides glomerulonephritis). The decrease in excretion of magnesium corresponds quite closely to the decrease in excretion of phenolsulphonphthalein but does not correspond to the alterations in excretion of xlose. We have found also that in nephrectomized animals and in animals with renal, and especially tubular, insufficiency the ingestion of magnesium sulphate causes a tremendous and rapid rise in plasma magnesium, sufficient even to bring them into a state of coma. Coma occurred whenever the plasma calcium reached or exceeded 17 mg of magnesium per hundred cubic centimeters of plasma. This exactly coincides with the level at which Neuwirth and Wallace⁴ and Taylor and Winter⁵ found coma setting in after the subcutaneous injection of magnesium salts.

We have therefore studied the effects of the ingestion of ordinary purgative doses of magnesium sulphate on the plasma magnesium and the general physical condition in a series of patients suffering from renal disease. In all these patients, just as in the nephritic animals, a tremendous rise in plasma magnesium occurred within from four to six hours after an ordinary purgative dose of magnesium sulphate (epsom salt) had been taken by mouth. While one such dose was not sufficient to raise the magnesium concentration in the plasma to the level at which coma sets in (about 17 mg of magnesium per hundred cubic centimeters of plasma) it often did rise to about two thirds of that concentration (from 9 to 11 mg) and a number of the patients did show a decidedly increased drowsiness or even a light coma accompanying the increase in plasma magnesium. The results are indicated in chart 1.

NOTES ON CASES

Normal—Plasma⁶ nonprotein nitrogen 30 mg, creatinine from 15 to 20 mg, magnesium from 1.85 to 2.09 mg. After taking from 20 to 30 Gm of epsom salt ($MgSO_4 \cdot 7H_2O$) average increase 0.24 mg, maximum increase, 0.4 mg. Excreted in urine phenolsulphonphthalein, from 60 to 80 per cent in two hours; magnesium excreted in twenty-four hours from 40 to 44 per cent (average 42.6 per cent) of the magnesium ingested.

HIGH PLASMA MAGNESIUM

CASE 1—*Subacute glomerulonephritis*. W. A., a woman aged 41 in the Minneapolis General Hospital complained of edema. Plasma nonprotein nitrogen 88, creatinine, 5.5, magnesium, 2.98, calcium, 11.3. Urine phenolsulphonphthalein 39 per cent. After 25 Gm of epsom salt by mouth, plasma magnesium 5.5, calcium 13.0. Magnesium excreted in twenty-four hours 23.8 per cent. Little effect on mental activity.

⁴ Neuwirth I. and Wallace G. B. J. Pharmacol. & Exper. Therap. 35: 171 (Feb.) 1929.

⁵ Taylor W. F. and Winter J. E. J. Pharmacol. & Exper. Therap. 35: 435 (April) 1929.

⁶ Amounts in plasma are always milligrams per hundred cubic centimeters.

From the Department of Pharmacology, University of Minnesota.

This paper was announced for presentation before the Section on Pharmacology and Therapeutics of the American Medical Association at the Milwaukee Session, June 15, 1933.

This investigation was made possible by a grant of funds from the Therapeutic Research Committee of the American Medical Association. Most of the patients on whom the observations were made were in the medical service of Dr. Hohart A. Reimann at the University of Minnesota Hospital and of Dr. George E. Fahr at the Minneapolis General Hospital. One was from the private practice of Dr. Charles B. Wright and three from the neurologic service of Dr. Joseph C. Michael at the Minneapolis General Hospital, all of whose cooperation is deeply appreciated. Preliminary reports have been published in Proceedings of the American Society for Clinical Investigation (J. Clin. Investigation 11: 841 [July] 1932; 12: 983 [1933]), Proceedings of the American Society for Pharmacology and Experimental Therapeutics (J. Pharmacol. & Exper. Therap. 48: 277 [1933]), and Proceedings of the Society for Experimental Biology and Medicine (Proc. Soc. Exper. Biol. & Med. 30: 996 [1933]).

CASE 2—Nephrosis 1, a woman aged 25, in the Minneapolis General Hospital, was mentally alert Plasma nonprotein nitrogen 73, creatinine, 47 magnesium, 298, calcium, 113 Urine phenolsulphonphthalein 29 per cent Mentally active After 20 Gm of epsom salt by mouth Plasma magnesium, 775 calcium 149 Urine magnesium excreted, 217 per cent Listless and drowsy

CASE 3—Acute glomerulonephritis M R a man aged 33 in the University Hospital with a blood pressure of 150 systolic, 100 diastolic, was mentally alert Plasma nonprotein nitrogen 60, creatinine, 49, magnesium, 187, calcium, 98 Urine albumin + +, phenolsulphonphthalein 39 per cent After 30 Gm of epsom salt by mouth Plasma magnesium 79 calcium 148 Urine magnesium excreted, 263 per cent Near coma, vomiting

CASE 4—Acute glomerulonephritis K, a woman aged 57, in the Minneapolis General Hospital, with a blood pressure of 170 systolic, 115 diastolic was mentally active Plasma nonprotein nitrogen 98, creatinine 89 magnesium, 273 calcium 119 Urine albumin + + +, phenolsulphonphthalein, 59 per cent After 20 Gm of epsom salt by mouth Plasma magnesium, 922, calcium, 157 Urine magnesium, 207 per cent Very drowsy, near coma

CASE 5—Chronic glomerulonephritis L J a woman, aged 35, in the University Hospital was inactive and drowsy Plasma nonprotein nitrogen, 136, creatinine, 12, magnesium, 39, calcium, 199 Urine albumin + + +, phenolsulphonphthalein, 26 per cent After 25 Gm of epsom salt by mouth Plasma nonprotein nitrogen 136, creatinine, 12, magnesium, 165 per cent Light coma

CASE 6—Chronic glomerulonephritis R A, a man, aged 60 in the Minneapolis General Hospital, with a blood pressure of 190 systolic, 125 diastolic, was mentally alert Plasma nonprotein nitrogen, 185, creatinine, 175, magnesium, 478, calcium 152 Urine albumin + + + +, phenolsulphonphthalein, 15 per cent After 25 Gm of epsom salt Plasma magnesium, 1035, calcium, 235 Urine magnesium, 10 per cent Light coma, hard to awaken

1975 Urine albumin + + +, phenolsulphonphthalein 15 per cent After 30 Gm of epsom salt by mouth Plasma magnesium 105, calcium, 241 Urine magnesium, 185 per cent Very drowsy

CASE 8—Acute glomerulonephritis E R, a woman, aged 39, in the University Hospital, with a blood pressure of 150 systolic 110 diastolic, was very alert Plasma nonprotein nitrogen, 100,

Chart 2—Observations in cases showing low plasma magnesium Legends have same significance as in chart 1

Chart 1—Observations in cases showing high plasma magnesium Urine magnesium = percentage of ingested magnesium excreted in urine in twenty four hours Before magnesium sulphate = milligrams of magnesium per hundred cubic centimeters of plasma before taking epsom salt (MgSO₄ 7H₂O) by mouth After magnesium = milligrams of magnesium per hundred cubic centimeters of plasma from four to six hours after taking epsom salt by mouth Words below the cross hatched lines refer to mental condition before taking epsom salt those above the solid line represent mental condition from four to six hours after taking epsom salt

CASE 7—Acute glomerulonephritis E P, a man, aged 43, in the Minneapolis General Hospital with a blood pressure of 165 systolic, 110 diastolic, was mentally alert Plasma nonprotein nitrogen, 85 creatinine, 875, magnesium, 575, calcium,

creatinine 9 magnesium 249 calcium 110 Urine albumin + + +, phenolsulphonphthalein 275 per cent After 30 Gm of epsom salt Plasma magnesium, 1075, calcium, 178 Drowsy

CASE 9—Chronic glomerulonephritis E L, a woman, aged 27, in the University Hospital, with a blood pressure of 200 systolic 135 diastolic was alert Plasma nonprotein nitrogen, 265, creatinine, 23 magnesium 41, calcium, 169 Urine albumin + + + + phenolsulphonphthalein, 12 per cent After 20 Gm of epsom salt by mouth Plasma magnesium, 1091, calcium, 185 Urine magnesium, 1535 Very drowsy, difficult to awaken

CASE 10—Acute glomerulonephritis O L, a man, aged 58, in the University Hospital with a blood pressure of 185 systolic, 140 diastolic, was listless Plasma nonprotein nitrogen, 1955 creatinine, 253, magnesium, 425, calcium, 195 Urine albumin + + +, phenolsulphonphthalein 12 per cent After 30 Gm of epsom salt by mouth Plasma magnesium, 1132 calcium 259 Urine magnesium, 175 per cent Hard to awaken, light coma

CASE 11—Chronic glomerulonephritis J J, a woman aged 62, in the University Hospital, with a blood pressure of 175 systolic 125 diastolic, near coma Plasma nonprotein nitrogen 215, creatinine 25, magnesium 893, calcium, 197 Urine albumin + + +, phenolsulphonphthalein, 128 No epsom salt given

CASE 12—Subacute glomerulonephritis O J, a woman aged 31, in the University Hospital, was very dull and listless Plasma nonprotein nitrogen 190 creatinine, 22, magnesium 90 calcium 240 Urine albumin + + + +, phenolsulphonphthalein, 17 per cent

CASE 13—Acute glomerulonephritis F S a man aged 52 in the University Hospital, with a blood pressure of 190 systolic 115 diastolic, was very drowsy Plasma nonprotein nitrogen, 190 creatinine 215, magnesium, 130, calcium, 220 Urine albumin + + + + phenolsulphonphthalein, 5 per cent, total urine 150 cc Died Autopsy showed arteriosclerotic kidneys

Since a single ordinary dose of epsom salt by mouth can raise the concentration of magnesium in the blood of nephritic patients to two thirds of the concentration at which coma sets in and since with larger doses it is easy to induce coma in nephritic animals, it seems probable that a few repeated doses of epsom salt would induce coma in the patients. It is therefore most probable that there are every year in the United States many hundreds of cases of coma occurring in nephritic patients which are diagnosed uremic coma but which in reality are magnesium coma caused by the use of epsom salt as a purgative. Since experimental animals could be brought out of this coma instantly and their lives could be prolonged by the intravenous injection of calcium chloride the intravenous injection of calcium chloride would probably restore such patients to consciousness.

We are not stating, nor do we think, that all or even most cases of uremic coma are due to magnesium intoxication, but we are merely calling attention to the fact that a condition of coma easily mistaken for uremic coma can be induced in nephritic patients by epsom salt purgation. Magnesium citrate would unquestionably have the same effect.

Our results in no way contradict those of Blackfan and his collaborators,⁷ who have administered magnesium sulphate intravenously for the control of uremic convulsions, or those of Dorsett⁸ and McNeile and Vruwink⁹ for eclamptic convulsions. Since they gave intravenously in carefully controlled doses only sufficient magnesium sulphate to produce subsidence of the convulsions, they stopped the administration as soon as a sufficiently high level of magnesium concentration in the blood had been reached. However, when the drug is administered by mouth and absorbed continuously from the intestine without regard to its concentration in the blood, this level can easily be exceeded.

Since our experiments on animals with renal insufficiency have shown that coma cannot be induced by tremendous doses of sodium sulphate it would appear that sodium sulphate should be the saline purgative of choice in patients with renal disease.

Our experiments on animals¹⁰ showed also that animals whose plasma magnesium was only slightly raised (to 5 mg or more) were much more sensitive than normal animals to ordinary doses of morphine. This explains Dr Osler's old aphorism that "in severe nephritics and very old persons morphine should be given with caution." Epsom salt was Dr Osler's favorite saline purgative and was administered almost as a routine in his wards at Johns Hopkins Hospital.

LOW PLASMA MAGNESIUM (HYPMAGNESEMIA)

Since Kruse, Orent and McCollum¹¹ have induced a form of tetany in rats that were raised on a diet free from magnesium it seemed probable that cases showing convulsions or other conditions of increased neuromuscular activity would be encountered clinically in which the plasma magnesium is low.

We have encountered thus far ten such clinical cases, in each of which convulsions or muscular twitchings were present. The data of these cases are shown in chart 2.

CASE 14—*Chronic glomerulonephritis, hypertension and convulsions*. S, a woman, aged 53, at the University Hospital, complained of edema of the legs and arms, and of intermittent general muscular twitchings. Plasma nonprotein nitrogen, 200, creatinine, 15, magnesium, 0.95, calcium 10.8. Urine albumin + + +, phenolsulphonphthalein, 12 per cent. After 20 Gm of epsom salt by mouth. Plasma magnesium, 3.3, calcium 11.9. No more twitching.

CASE 15—*Chronic glomerulonephritis*. C O, a man, aged 36 in the Swedish Hospital, had general muscular twitching. Plasma nonprotein nitrogen, 76.5, creatinine, 5.5, magnesium, 1.09, calcium, 9.3. Urine albumin + +, phenolsulphonphthalein 22 per cent. After 20 Gm of epsom salt by mouth. Plasma magnesium, 3.78, calcium, 13.0. No twitching.

CASE 16—*Chronic glomerulonephritis*. P S, a man, aged 51 at the Minneapolis General Hospital was nervous, and had general muscular twitching. Plasma nonprotein nitrogen, 55.0, creatinine, 4.3, magnesium, 1.31, calcium, 16.7. Urine albumin + +, phenolsulphonphthalein, 33 per cent. After 25 Gm of epsom salt by mouth. Plasma magnesium, 4.0, calcium, 17.3. No twitching resting quietly.

CASE 17—*Eclampsia*. I H, a woman, aged 47, at the University Hospital, was pregnant and had frequent headaches and general muscular twitchings passing into convulsions. Plasma nonprotein nitrogen 33, creatinine, 2.1, magnesium, 1.0, calcium 11.3. After 25 Gm of magnesium sulphate by mouth. Plasma magnesium, 5.87, calcium, 14.13. No twitching or convulsions.

CASE 18—*Glomerulonephritis*. W C, a man aged 51, at the Northwestern Hospital, had violent convulsions (uremia) and a blood pressure of 160 systolic, 100 diastolic. Plasma nonprotein nitrogen 175, creatinine 18, magnesium, 0.9, calcium, 24.0. No epsom salt was given.

CASE 19—*Parathyroid deficiency*. H, a man aged 61, in the University Hospital with a blood pressure of 130 systolic, 90 diastolic, had marked convulsions. Plasma nonprotein nitrogen, 30, creatinine, 1.8, magnesium, 0.93, calcium, 7.0. No epsom salt was given.

CASE 20—*Possible cerebral injury*. M, a woman, aged 20, in the University Hospital, had general muscular twitching. The physical examination was negative and an encephalogram was negative. Plasma magnesium 1.14, calcium, 10.0. No epsom salt was given.

CASE 21—*Epilepsy (?)*. MCK, a boy aged 12 years, in the University Hospital had intermittent twitching of the upper and lower extremities every two or three days, followed by sleep for several hours (possible epilepsy). Plasma magnesium, 1.16, calcium, 11.8. No epsom salt was given. Was relieved later by ketogenic diet.

CASE 22—*Parathyroid deficiency*. B, a woman, aged 42, in the University Hospital had light convulsion. The laboratory report was negative. Plasma magnesium, 1.35, calcium, 9.0. No epsom salt was given.

CASE 23—*Epilepsy*. E E, a woman, aged 35 in the Minneapolis General Hospital, had epileptic attacks every two to three months and was restless between attacks. The laboratory report was negative. Plasma magnesium, 1.77, calcium, 12.9. No epsom salt was given.

CASE 24—*Epilepsy*. D, a woman, aged 42 had epilepsy (grand mal occasional attacks). The laboratory report was negative. Plasma magnesium, 1.8, calcium, 13.7. No epsom salt was given.

It will be noted that two of these are cases of parathyroid tetany. This accords with the experimental results of McCollum and his collaborators and with the clinical observations of Howland and Marriott,¹² Denis

and Talbot¹³ and Bulger and Gausmann,¹⁴ who also found low blood magnesium in some but not in all cases of parathyroid tetany. Moreover, Salvesen and Linder¹⁵ and Lang¹⁶ found that removal of the parathyroid glands in animals caused no change in blood magnesium.

Three of our patients with low plasma magnesium suffered from idiopathic epilepsy. Denis and Talbot also had reported two. But since we have also found practically normal plasma magnesium in four epileptic patients (177, 197, 213 and 26 mg respectively) it is evident that a low plasma magnesium is not a constant finding in this disease. It is possible, however, that there may be a variability in the plasma magnesium of such individuals and that periods of low magnesium may precede and accompany the attacks. We are at present engaged in a further study of this question.

Four of the patients with low plasma magnesium had glomerulonephritis. That this should occur in spite of the diminished ability of the nephritic kidney to excrete magnesium may seem paradoxical, but since such patients are usually on a milk or at least on a soft diet, it is evident that their intake of magnesium salts can easily remain below their power to excrete magnesium. When the usual purgative dose of epsom salt was administered by mouth to three of these patients, the plasma magnesium rose within from four to six hours from the previous concentrations of 0.95, 1.09 and 1.37 mg per hundred cubic centimeters, respectively, to 3.3, 3.78 and 4.0 mg, nearly double the normal concentration, and simultaneously with this increase in magnesium the twitchings or convulsions subsided.

Denis and Talbot have reported also one case of lobar pneumonia and one case of bronchopneumonia, both of which presented convulsions and one case of chorea with low blood magnesium. However, we have had a case of chorea with normal plasma magnesium (2.13 mg) and normal calcium (12.2 mg).

In view of the cases here reported, it is evident that there is a clinical syndrome associated with low plasma magnesium accompanied by a condition of hyperirritability of the neuromuscular system often associated with muscular twitchings or convulsions. These cases are probably more common than has been realized.

At least in the patients whose kidneys are pathologic the twitchings or convulsions can be relieved by the administration of a purgative dose of epsom salt by mouth.

SUMMARY AND CONCLUSIONS

1 When normal individuals take epsom salt by mouth they excrete about 40 per cent of the ingested magnesium in the urine in twenty-four hours but the concentration of magnesium in the blood plasma does not rise appreciably.

2 The concentration of magnesium in the plasma may vary greatly under clinical conditions.

3 There is a clinical syndrome of high plasma magnesium (hypermagnesemia) accompanied by somnolence or coma.

4 This may be induced in patients with renal insufficiency by the oral administration of one or more purgative doses of epsom salt.

5 Many cases of coma in nephritic patients diagnosed uremic coma, may be simply magnesium coma.

induced by epsom salt purgation. From such coma patients could probably be awakened by intravenous calcium chloride.

6 Sodium sulphate is preferable to epsom salt for patients with renal insufficiency.

7 There is a clinical syndrome of low plasma magnesium (hypomagnesemia) accompanied by muscular twitching or by convulsions.

8 When this occurs in patients with renal insufficiency, the twitchings or convulsions are relieved by oral administration of epsom salt.

SUDDEN DEATH FROM DINITROPHENOL POISONING

REPORT OF A CASE WITH AUTOPSY

FRANK E. POOLE, M.D.

AND

ROBERT B. HAINING, M.D.

LOS ANGELES

In an article in July 1933 Cutting, Mehrtens and Tainter¹ stressed the remarkable potency of dinitrophenol as a metabolic stimulant and brought forward evidence (based on extensive animal experimentation and a small series of human cases) that its administration in proper dosage accelerates cellular metabolism apparently without harmful effects. They therefore proposed its carefully supervised clinical use in the treatment of obesity, hypothyroidism and similar depressed metabolic states.² However, because of its known toxic properties they warned that "there are limitations to and possible dangers from the use of this drug clinically. It should be used only under strictly controlled conditions." This warning was emphasized in an editorial³ and by a preliminary report of the Council on Pharmacy and Chemistry of the American Medical Association⁴ which appeared in the same issue (July 15) of THE JOURNAL. The editorial stated that "a drug with the potency and effects of dinitrophenol is a two-edged sword with appalling possibilities for harm as well as for good" and warned that "certainly for the present, at least such investigations should be largely limited to controlled studies in hospitals by physicians competent in evaluating the effects of the drug and with laboratory facilities capable of accurately determining blood, body tissue and other changes."

In a series of fourteen cases of obesity treated with dinitrophenol as recommended by Cutting, Mehrtens and Tainter, Anderson, Reed and Emerson⁵ observed one case of what they term allergic "qualitative idiosyncrasy" with striking cutaneous manifestations. This patient had received an oral dose of 39.3 mg per kilogram of body weight over a period of fourteen days and the authors do not regard this as an instance of repeated small therapeutic doses producing toxic effects similar to those described for larger doses. The probability of an allergic etiology is strengthened by the early work of Mayer (reviewed by Perkins⁶). Mayer

studied the effects of dinitrophenol on munitions workers who handled the material during the manufacture of explosives. Until hygienic preventive measures were instituted, many of these individuals developed dizziness, headache, vomiting, high fever, night sweats, and similar disturbances, and in some instances sudden death occurred. Mayer discovered that the exposed workers evinced wide variations in their susceptibility to the dinitrophenol. These variations were wholly unpredictable, except that persons with chronic rheumatism, tuberculosis, alcoholism, renal disorders and hepatic disease seemed to have a lessened resistance to the substance. Undoubtedly Cutting, Mehrtens and Tainter¹ had these experiences in mind when they commented: "Finally, the possibility of an idiosyncrasy such as an unusual sensitivity or atypical response to the drug should be kept in mind, although we have not seen unusual reactions. In view of these things we urge that, for the present, dinitrophenol be used only as an experimental therapeutic procedure in carefully selected patients under close observation by the physician."

Further proof that dinitrophenol may possess treacherous toxic possibilities was afforded by the work of Masserman and Goldsmith.⁶ They selected eighteen patients between 18 and 40 years of age, free from discoverable organic disease, whose psychobiologic underactivity was evidenced by sluggishness, passivity and apathy. These patients were given 60 mg of sodium dinitrophenol daily and the dose was increased 60 mg every third day to a maximum of 5 mg per kilogram in divided doses, or until adverse symptomatology contraindicated further treatment. Six of the eighteen patients showed some improvement in their mental state. The results were indeterminate in eight cases. Toxic effects characterized by fall in blood pressure, tachycardia, acidosis and progressive stupor were observed in five cases, in one of which death occurred. These authors conclude that "dinitrophenol may possess a cumulative toxic activity which is not heralded by excessive sweating, dermatitis or pyrexia but which seems, on the other hand, to be characterized by a fall in the blood pressure, tachycardia, the onset of acidosis, and progressive torpor."

In spite of these repeated warnings it is not surprising that the use of dinitrophenol has not been restricted to the carefully controlled conditions urged by every one who has written authoritatively on the subject. Perhaps such restriction is too much to expect when an inexpensive chemical holds out promise of being a delightfully simple answer to the prayers of many men as well as of maidens. He who points a comparatively short and easy route to weight reduction will be rewarded with the rapturous gratitude of obese patients, and the patient with a passion for slimming will addict himself with pathetic fanaticism to a method which may spare him the safer but more uncomfortable procedures. It appears that within the past few months dinitrophenol has been sold and ingested, with and without prescription, in alarming quantities. We have investigated a number of drug stores in this locality, and the number of prescriptions for dinitrophenol to be seen on file at the end of a single day is disquieting. Worse than this, however, is the practice on the part of some pharmacists of selling the substance over the counter to any and every applicant, without prescription and without ade-

quate precautions. In the case we are recording, the dinitrophenol was sold to a girl who had heard of the remedy from a friend and the label merely bore the pharmacist's instructions of how many capsules to take each day. This, we believe, is the third reported instance of death due to dinitrophenol. One case has been recorded by Masserman and Goldsmith⁶ and one by Geiger. Geiger's case, however, was apparently a proved result of heavy overdosage.

REPORT OF CASE

History.—M. B., a white woman, aged 25, single, weighing 147 pounds (66.7 Kg.) had never been seriously sick but in recent years for pure esthetic reasons, had worried about her obesity. She was employed as a social service worker (in a county health center) and in June 1933 she consulted one of the physicians at the health center, complaining of obesity, "lack of pep" and dysmenorrhea. At this time her basal metabolic rate was found to be -12 . The physician prescribed desiccated thyroid one-fourth grain (0.016 Gm.) three times a day and the patient continued to take thyroid tablets probably quite constantly, until March 2, 1934. Since her work brought her into daily contact with capable physicians, it may reasonably be assumed that during this period she at no time complained of any alarming symptoms of thyroid overdosage. She lived with her parents, who assure us that she appeared to them to be in good health and good spirits.

During the afternoon of March 2, 1934, her duties took her to the office of Dr. F., with whose office nurse Miss W., she fell into a conversation. She confided to Miss W. that she wished to reduce her weight and that she had been taking thyroid preparations for some months with altogether made quite effect. It happened that during lunch, that day, Miss W. had heard some doctors discussing a new reducing agent—dinitrophenol—and had herself bought some capsules of the compound from the pharmacist in a nearby drug store. Miss W. told of her discovery and later was informed by the pharmacist that the patient purchased some dinitrophenol from him on the same day (March 2). Miss W. is positive that the patient had never heard of dinitrophenol until she informed her of the substance and of the properties claimed for it. The parents are certain that their daughter ingested her first dinitrophenol capsule March 2.

The pharmacist, Mr. B., states that he sold the patient thirty-five capsules of dinitrophenol (Eastman Kodak Company's 24 Sodium Dinitrophenol) each capsule containing 3 grams (0.2 Gm.). The box and what remain of the capsules are in our possession. The label on the face of the box is imprinted with the name of the pharmacy and bears typewritten instructions: "one capsule the first day, two the second three the third and four thereafter." The contents of the capsules are not named or described.

On Monday, March 5, the patient met Miss W. again and told her that she was taking dinitrophenol and that she "wasn't feeling so well." She attributed her feelings to the fact that the action of the thyroid had not yet "worn off" and that in some way the combined action of the dinitrophenol with the thyroid was producing uncomfortable results. However, she opined that the thyroid effect would soon disappear and did not propose curtailing her dinitrophenol program.

Tuesday, March 6, while at work, she complained of headache, backache, weakness, dizziness, shortness of breath and excessive perspiration. Her companions assured her that the weather was to blame, and she did not leave work.

Wednesday, March 7, she felt unable to go to work but did not stay in bed, attributing her symptoms to an oncoming cold. During the day the parents noticed that she took two of the dinitrophenol capsules. About 6 p. m., she became restless and complained of the increasing severity of her headache, pains in legs and arms and of a sensation of "burning up." She appeared flushed, perspired profusely, and this so impressed a friend who called about 8 p. m. that he anxiously volunteered to go and buy a thermometer. Instead, the parents decided to call a physician. The physician did not know that the girl had been taking dinitrophenol but her condition appeared to him

6 Masserman, J. H. and Goldsmith, Harry. Dinitrophenol: Its Therapeutic and Toxic Actions in Certain Types of Psychobiologic Underactivity. *J. A. M. A.* 102: 523-525 (Feb. 17) 1934.

7 Geiger, J. C. A Death from Alpha Dinitrophenol Poisoning. *J. A. M. A.* 101: 1333 (Oct. 21) 1933.

so alarming that he referred her immediately to the Los Angeles County General Hospital. All this time she complained more and more bitterly of the sensation of "burning up" and kept calling for water. She vomited violently several times and became comatose about 1 a m while en route to the hospital in an ambulance. In removing the patient from the ambulance, the driver noticed that the sheets and cot were wet with perspiration.

The family history was not significant. The patient's childhood diseases were measles, pertussis and chickenpox. Her menses began at the age of 14 and were always somewhat irregular and attended by considerable discomfort. As already mentioned she visited a physician in June 1933, complaining of obesity, "lack of pep" and dysmenorrhea.

Physical Examination (in hospital admitting room 330 a m March 8).—The temperature was 101.8 F, pulse 140 respirations 56. The blood pressure was not recorded. Dr. Hauser, who examined the patient, states that he is sure the temperature (recorded by a nurse) was higher than the record shows. Probably such a high respiratory rate would preclude an accurate determination of the mouth temperature. (However, in the fatality observed by Masserman and Goldsmith⁸ the highest rectal temperature was 102, just before death.)

The patient was comatose and could not be aroused but was restless perspiring profusely and breathing deeply and rapidly. The extremities were flaccid and no reflexes could be elicited. The pupils were regular but failed to react to light or in accommodation. The heart rate was very rapid, and auricular fibrillation was suspected.

In the admitting room a tentative diagnosis was made of poliomyelitis and the patient was sent to the communicable disease unit, where preparations were immediately made to do a spinal puncture. However, the patient died suddenly at 4:35 a m, before the spinal puncture could be completed. Artificial respiration, caffeine sodiobenzoate and intracardiac epinephrine were given with no response. The body came to autopsy ten hours after death, having been well preserved at optimal temperature.

Autopsy.—Livor mortis was marked over the head, neck, upper extremities and thorax. Moderate rigor mortis was present.

The pupils were equal and regular each measuring 5 mm in diameter. The sclerae were distinctly yellowish (causing us to suspect jaundice) and the conjunctival vessels were engorged. Fat over the sternum measured 3 cm in thickness and over the abdomen 5 cm.

The meninges appeared normal. Coronal serial sections through the brain revealed no gross evidence of pathologic change.

The pleural surfaces were smooth and glistening and the pleural cavities contained no fluid. The right lung weighed 480 Gm and the left 380 Gm. There was no evidence of consolidation or bronchopneumonic patching. All lobes were crepitant, but cut surfaces of the lungs at all levels appeared hyperemic, and bloody fluid exuded freely on the slightest pressure. The bronchi contained no excessive or abnormal secretion.

The heart was normal in size and shape and weighed 220 Gm. The pericardium was smooth and glistening. No endocardial lesions were present. The valve orifices were not dilated or narrowed and the valve leaflets showed no thickening. The myocardium was somewhat flabby. The coronary vessels were thin walled and patent throughout their course. The intimal surface of the aorta was pale and smooth and presented no evidence of syphilitic or atherosclerotic changes.

The esophagus was normal. The stomach contained about 300 cc of faintly blood-tinged fluid. The gastric mucosa was intact and gave no indication of having been in contact with any irritating or corrosive material. However, there were many reddish blue areas of discoloration apparently due to small submucosal hemorrhages and toward the cardia these areas were confluent, so as to impart to this region a uniformly bluish hue. The duodenum and upper half of the jejunum also showed some of these small hemorrhages, which probably represent the effects of much violent vomiting.

The liver was dark brown, firm, and weighed 1,400 Gm. The cut surface had a finely mottled appearance, which was by no

means marked enough to suggest chronic passive congestion. The gallbladder was filled with brown bile, and the extrahepatic biliary passages were patent.

The spleen was slightly larger than normal, dark purple, quite firm, and weighed 190 Gm.

Multiple sections through the pancreas revealed no gross evidence of pathologic changes.

The kidneys were normal in size and shape and together weighed 250 Gm. The capsules stripped with ease, leaving a smooth, somewhat purplish surface. The cortex was of normal thickness. The suprarenals showed no remarkable change.

The fimbriated ends of the fallopian tubes were sealed against the ovaries by rather firm adhesions and the tubes were slightly distended and contained a small amount of turbid fluid. The ovaries and uterus appeared normal.

The urinary bladder contained 300 cc of clear urine which was strikingly yellow, the color being especially noticeable in the foam when the urine was agitated. The urine was aspirated before the bladder was opened and saved for examination. The bladder itself appeared normal.

Unfortunately, dinitrophenol poisoning was not suspected at the time the urine was examined so that no chemical tests were made to determine the presence of the compound in the urine. The reaction of the urine was alkaline. The specific gravity was 1.025. Examination revealed albumin, two plus bile pigments, negative sugar, acetone and diacetic acid, negative, benzidine test for occult blood, negative. Microscopic examination revealed a few granular casts.

Blood chemistry post mortem showed creatinine 2.5.

Blood culture post mortem gave no growth after twelve days' incubation.

MICROSCOPIC EXAMINATION

Fortunately, consent for autopsy was obtained almost immediately, and in the interval the body was kept in a refrigerated cubicle. Hence there were practically no postmortem changes and it was possible to make accurate interpretations of microscopic sections.

The convoluted tubules of the kidneys showed the most striking changes. They were in all stages of degeneration. In some places there was only cloudy swelling and pyknosis, but most of the tubules showed actual necrosis. Between the tubules the interstitial tissue appeared edematous. There was much fine hematogenous pigment in the tubular epithelium especially in the bases of the cells (fig 1). The capillary and arterial loops in the glomeruli were distended in places. The blood vessels in the pyramids were markedly distended and there were occasional small hemorrhagic areas.

There were very extensive areas of disintegration and separation of liver cells, apparently by fluid. These areas were confined to the periphery of the lobules; the central portions being unaffected (fig 2). As a result of these peculiar changes, each lobule appeared widely separated from the adjacent lobules. The cytoplasm of the liver cells in the periportal areas was granular and the nuclei were pyknotic (fig 3).

The splenic pulp was unusually full of blood.

The small blood vessels of the mucosa of the stomach were markedly distended and in places actual small hemorrhages seemed to have occurred into the mucosa. The mucosa appeared very edematous, and the glandular epithelium was disintegrated and contained an abnormal number of lymphocytes.

The pancreatic tissue was unusually well preserved, and this probably constitutes good evidence that changes seen in other organs cannot be assumed to be due to postmortem changes.

There was marked congestion of the alveolar walls of the lungs. In places there was considerable edema in the alveoli.

There was marked segmentation and fragmentation of the cardiac muscle fibers in all sections (fig 4). The tissue of the spinal cord, pons and medulla was hyperemic and the capillaries were uniformly distended with blood. There was no perivascular edema and no perivascular round cell infiltration. Section through the pons at the level of the eighth nerve showed slight ganglion cell degeneration.

CHEMICAL TESTS OF TISSUE

A measured quantity of kidney tissue was acidified and steam distilled for approximately one hour. The resulting distillate was colorless but turned canary yellow on the addition

of ammonium hydroxide. The color disappeared again when acid was added.

Since dinitrophenol is a standard indicator whose pH range is known, the indicator properties of a solution of the distillate were compared with those of a solution of dinitrophenol diluted so as to have the same intensity of color. The color changes occurred at approximately the same pH value.

In accordance with tests described by the French workers⁸ 200 Gm of liver tissue was immersed in 95 per cent alcohol for five days, and the resulting extract displayed the same indicator properties as the kidney distillate.

Both the solutions thus obtained from kidney and liver gave a positive Le Mithouard reaction. This test and many others are described in detail by Magne, Mayer and Plantefol.⁸

Finally 400 cc of the kidney extract was concentrated by evaporation to 10 cc. This concentrate gave a strongly positive reaction when tested according to the method of Derrien. The technique of the reaction of Derrien is quoted from the French workers by Anderson, Reed and Emerson.⁴

COMMENT

Following the autopsy we were unable to propose so much as an intelligent guess regarding the cause of death, therefore the patient's relatives were questioned regarding the possibility of her having ingested mushrooms (several deaths from mushroom poisoning having been reported in this district recently) and regarding any medicine she might have been taking. The mushroom theory was ruled out, but the father did recall seeing her take some "pink capsules" and these he brought to us the next day. The capsules contained a yellow crystalline powder and this immediately called to our minds the peculiar yellowness of the urine, which unfortunately, we had by this time discarded. A young obese woman might have been trying to reduce her weight and might have been using dinitrophenol. We compared the substance in the capsules with a sample of dinitrophenol and they appeared identical. The melting point was found to be 114 F. The substance was readily soluble in water, and the solution became colorless on the addition of acid and yellow again when alkalinity was restored. Later we talked with the pharmacist from whose store the purchase was made. He confirmed our presumption that the capsules contained dinitrophenol and referred us to Miss W., a friend of the deceased. From these persons and from the family we were able to piece together and substantiate the history as related.

In the box brought to us by the father were nineteen capsules of dinitrophenol. Since thirty-five capsules were sold to the deceased, she obviously took sixteen capsules between March 2 and March 7 inclusive. This harmonizes exactly with the instructions on the label to take "one capsule the first day (March 2), two the second, three the third, and four thereafter." It may reasonably be assumed that she took one on Friday (March 2), two on Saturday, three on Sunday, four on Monday, four on Tuesday, two Wednesday morning and none Wednesday afternoon, when her symptoms became more prominent. Each capsule contained 180 mg of dinitrophenol, so that a total dose of 2,880 mg was taken in a period of five days.

It seems to us indisputable that this girl's sudden death is attributable directly to the action of dinitrophenol.

THERAPEUTIC DOSAGE OF DINITROPHENOL

Cutting, Mehrtens and Tainter¹ gave nine patients daily oral doses of from 3 to 5 mg per kilogram of body

weight with no ill effects. In their series of fourteen cases, Anderson, Reed and Emerson⁴ gave fourteen patients daily oral doses of about 3 mg per kilogram, with one case of sublethal toxicity. Apparently a daily oral dose of from 3 to 5 mg per kilogram is the accepted safe therapeutic dosage.

This figure was based largely on animal experimentation. Tainter and Cutting⁹ found that the average fatal dose for 50 per cent mortality in rats, dogs and rabbits was between 20 and 30 mg per kilogram. Magne, Mayer and Plantefol⁸ concluded from studies of a large and varied series of animals that the reliable fatal dose was about 50 mg per kilogram. To human subjects, Mehrtens and Tainter¹ have given as high as 10 mg per kilogram for a small number of doses.

When our patient took four capsules a day (or 107 mg per kilogram daily) she was consuming more than the recommended therapeutic dose but was well below the limit of what is thought to be the fatal dosage.

IDIOSYNCRASY TO DINITROPHENOL

From the evidence available it seems probable that as compared with animals human beings have a more variable and more unpredictable susceptibility to dinitrophenol. Magne, Mayer and Plantefol⁸ found that only a small number of animals succumbed to a dose smaller than the generally effective lethal dose for their particular kind. Tainter and Cutting⁹ also observed that the limit of tolerance was fairly regular within each animal species, though some species, particularly the pigeon, succumbed to a dose which other animals could tolerate with safety. While certain responses such as the fever were very variable in no single instance, apparently, did an experimental animal die unexpectedly as a result of a dose of dinitrophenol which for other animals of the same species was demonstrably well below the safety limit.

This relative uniformity of tolerance is apparently not true of the human subject and if not true it is the point to be stressed. Naturally there is no large well controlled series of human cases on which a conclusion might be based. But we have already pointed out that Mayer² discovered a striking variation in the susceptibility of the men and women who handled dinitrophenol in the French munitions factories during the war. A group of people doing the same type of work in identical surroundings often manifested responses varying apparently all the way from a complete absence of deleterious symptoms to sudden death. The preliminary report of the Council on Pharmacy and Chemistry³ points out that "these accidents grew so numerous that it was proposed at one time to abandon the manufacture of this compound despite the then great demand for it."

Aside from the small series of cases reported by Cutting, Mehrtens and Tainter,¹ the only carefully controlled clinical trials of dinitrophenol have been conducted by Anderson, Reed and Emerson⁴ who encountered one case of serious toxicity in a series of fourteen, and by Masserman and Goldsmith,⁶ who observed four cases of toxicity and one death in a series of eighteen. Perhaps the increasingly widespread and promiscuous use of the compound will have at least one good result. It may provide in an unpleasant manner evidence of the human responses to dinitrophenol. The case we are recording is the third fatal example of this probability.

⁸ Magne, H., Mayer, A. and Plantefol, L. *Ann. de physiol. et physiochim. biol.* 8: 1176, 1932.

⁹ Tainter, M. L. and Cutting, W. C. *Miscellaneous Actions of Dinitrophenol*. *J. Pharmacol. & Exper. Therap.* 49: 187-209 (Oct.) 1933.

The total dosage in this case (weight 67 Kg) was 288 Gm in five days. In the case recorded by Anderson, Reed and Emerson¹ (weight 79 Kg) the total dose was 315 Gm over a period of fourteen days. In both instances the total amount of dinitrophenol consumed was well within the estimated safety limits, and the victims probably each had an abnormal susceptibility

with dinitrophenol died within one minute. Hence while dinitrophenol seems beyond doubt to act by accelerating cellular oxidation, it cannot be shown to antagonize agents that depress cellular oxidation.

CLINICAL SIGNS AND SYMPTOMS

Probably one of the most treacherous properties of dinitrophenol is that it seems to induce a relative euphoria in subtoxic doses. Thus Cutting, Mehrtens and Tainter¹ observed that their nine patients treated for obesity "did not suffer from any deleterious symptoms, as a result of their reducing treatment. On the contrary, they felt better and more active than before." We suggest that this may be a treacherous property, because it seems to us that it may betray the patient into a false sense of well being. From our present understanding of the subject it is clear that the responses of a few patients cannot safely be used as a criteria for other individuals. For the present the only safety lies in confining the clinical use of the drug to very closely supervised cases.

Hyperthermia with profuse perspiration and what the French call "thermic dyspnea" seem to be the outstanding signs of toxicity. Cutting, Mehrtens and Tainter¹ found that, in a series of eight patients, single doses between 5 and 10 mg per kilogram provoked no changes in temperature, pulse or respiration but did cause copious sweating. Three single doses "of more than 10 mg per kilogram gave increases in temperature of 3 degrees C or more, in respiration of 15 to 30 per minute, and of pulse 20 to 30 per minute. The latter doses are considered too dangerous for routine use." Probably it is wise to stress this warning. The first sign of abnormal sweating or elevation of temperature (or

Fig 1—Section of kidney showing tubular degeneration

to dinitrophenol. The outstanding difference is that our patient had been taking thyroid for several months before she began to use dinitrophenol. There is a possibility, on which we are not competent to pass judgment, that the fatality was due to some vicious synergism between the action of dinitrophenol and of thyroid. It is more probable that our case represents, like that reported by Anderson, Reed and Emerson,⁴ an allergic idiosyncrasy to dinitrophenol.

The patient observed by Masserman and Goldsmith⁶ received 606 Gm in fourteen days, but since she weighed 130 Kg the dosage is not significantly greater, and she probably did not die of simple overdosage.

ACTION OF DINITROPHENOL

The work of Magne, Mayer and Plantefol⁸ is in agreement with that of Tainter and Cutting⁹ that in animals and men fever occurs from dinitrophenol administration as a result of increased tissue metabolism, apparently by a direct peripheral action on body cells. Carbohydrate seems to be singled out as the main fuel for this metabolic increase. Magne, Mayer and Plantefol showed that the rise in temperature is not due to action on the heat center, because they were able to produce it in poikilothermic animals, in anesthetized animals, in curared animals, in animals with the cord severed, and in isolated strips of muscle. Their final conclusion was that "dinitrophenol 1-2-4 seems to be a direct excitant of cellular oxidation."

Since cyanide inhibits cellular oxidation and dinitrophenol augments it, Tainter and Cutting⁹ injected cyanide into pigeons at the height of their response to an injection of dinitrophenol. Methylene blue (methylthionine chloride) can be shown successfully to antagonize a similar dose of cyanide, but the pigeons protected

Fig 2—Section of liver under low power showing peculiar separation of liver cells in the periphery of the lobule

according to Masserman and Goldsmith⁶ fall in blood pressure and tachycardia) should call for abrupt discontinuance of the medication, for, as Cutting, Mehrtens and Tainter¹ state, the "margin between the febrile and the fatal dose is narrow."

Various tests have been devised, especially by the French workers, for the detection of dinitrophenol in blood, urine and certain viscera. Their importance, for

the present, seems to lie mainly in helping to establish cause of death in a disputed case. According to Perkins, a persistence or increase in amount of dinitrophenol in the urine (measured by the Derrien test) should be considered a sign of intolerance. In our case it seems probable that Derrien's test would have been positive, since the urine was strikingly yellow. How-

Fig. 3—Section of liver under high power showing degeneration of liver cells in the periphery of the lobule

ever, in the case recorded by Anderson, Reed and Emerson, Derrien's test was repeatedly negative, so that it cannot be regarded as a means of testing allergic sensitivity to the compound.

TREATMENT OF DINITROPHENOL POISONING

Tainter and Cutting⁹ injected six rabbits with from 20 to 40 mg of dinitrophenol, and when the usual respiratory and temperature changes developed, the rabbits were given from 10 to 40 mg of morphine. The rise in temperature was checked and the respiratory rate returned to normal, but all the animals died. Other depressants, such as barbital and chloralose, were equally disappointing. These facts indicate that while morphine may be useful to counteract excitement and dyspnea (and is so recommended by Perkins⁶) it cannot be regarded as a true antidote and will not save life in a case of severe poisoning.

Tainter and Cutting⁹ then tried agents calculated to reduce muscular or cellular activity and to reduce local blood flow. All these agents, such as sodium gluconate, dextrose plus insulin, moniodoacetic acid, quinine and salicylate, were found ineffective in animals.

Whenever dinitrophenol is used clinically it should therefore be borne in mind that there is no known antidote and that, once the process of intoxication begins, no means of arresting it are available. The action of the agent cannot be opposed. At present one can merely try to support the organism through the crisis. Mayer⁵ found (in treating munitions workers) that this could best be done by giving massive intravenous injections of dextrose. In animals Tainter and Cutting⁹ found that the only measures which affected the mortality were administration of fluids, and cooling baths.

PATHIOLOGY OF DINITROPHENOL POISONING

Hundreds of experimental animals have been examined post mortem but no lesions peculiar to dinitrophenol poisoning have been described. Mayer⁵ in 1915 was the first physician who had the opportunity of studying tissues of human victims. He found that, while edema of the lungs and fatty infiltration of the liver may occur, there are no characteristic lesions.

Our case probably presents the first microscopic study of tissue taken at autopsy since Mayer's early work, and we have added very little. Even if the lesions we observed were unique, it would be rash to consider them pathognomonic on the strength of one case. However, the lesions in the kidney, liver and heart seem to us sufficiently arresting to warrant careful description. The pronounced tubular degeneration has been understressed and may signify that dinitrophenol acts on the kidney in a manner similar to other poisons, such as corrosive mercuric chloride and phosphorus. The peripheral spacing and early degeneration of liver cells seems to us a most unusual finding and is well seen in the photomicrograph. Fragmentation of the cardiac muscle fibers probably indicates the severity of the intoxication and a sudden, agonizing death.

CONCLUSIONS

1 Every one who has commented on the use of dinitrophenol has stressed the importance of restricting its clinical trials to carefully selected cases under constant supervision. However it appears that the compound is being widely popularized as a weight-reducing agent and is being bought and used with no competent direction. This seems highly deplorable in the present state of knowledge of human responses to dinitrophenol.

Fig. 4—Fragmentation and segmentation of heart muscle fibers

2 Thorough and extensive animal experiments have been performed (notably by Tainter and Cutting⁹ and by Magne, Mayer and Plantefol⁸) and the toxic effects and the fatal dosage for animals have been accurately determined. This work, however, must not be presumed on too freely in dealing with human beings and it can have no value whatever in predicting or preventing the occurrence of severe allergic manifestations.

3 There is no antidote for dinitrophenol poisoning. The only measures that have seemed to reduce the mortality in animals have been administration of fluids, and cooling baths. In dinitrophenol-poisoned munitions workers, Mayer found that intravenous injections of dextrose constituted the most effective treatment. This seems rational because of the marked loss of tissue glycogen that has been shown to occur. Morphine allays the excitement and the dyspnea and may check the rise in temperature, but it cannot halt the intoxicative process, and, in dogs poisoned with dinitrophenol, morphine does not affect the mortality.

4 In the case of sudden death from dinitrophenol poisoning reported, the victim heard of the compound from a friend and bought and used it without competent supervision. A physician was not consulted until a few hours before death.

5 The dosage in this case was high but within the presumed limits of safety, so the fatality should probably be regarded as an example of allergic idiosyncrasy.

6 Before taking dinitrophenol, the patient had been taking desiccated thyroid extract, one-fourth grain (0.016 Gm) three times a day for about one year. We do not know whether or how this has significance.

A CASE OF FATAL DINITROPHENOL POISONING

M. L. TAINTER, M.D.

AND

D. A. WOOD, M.D.

SAN FRANCISCO

In a short note recently published,¹ attention was drawn to a fatality that occurred from dinitrophenol poisoning. Since this drug is being widely used as a metabolic stimulant, and since the complete details of this case were available only to us, it seemed desirable to publish a full account of it, together with the pathologic observations. This case report will also emphasize the fact which we have consistently stressed,² namely, that careless or reckless use of this drug may have unfortunate consequences.

REPORT OF CASE

History—H. G., a man, aged 37, a graduate of a Vienna medical school but unlicensed to practice in this country, called on one of us (T.) to obtain information regarding dinitrophenol as a metabolic stimulant. He stated that he was suffering from general glandular dysfunction, including a hypopituitarism resulting from a previous sphenoiditis. His libido was gone and no therapy had been beneficial. On questioning, he admitted that the metabolic rate was normal and that he had little, if any, need of weight reduction, since he was not obese. The patient's account of his glandular dysfunction was neither tangible nor convincing. In addition, there was noticeable slurring of speech and eccentricities of manner, which aroused suspicion of some more definite disease process. He was therefore advised that the drug offered no prospect of benefit to him, since he needed neither to increase his metabolism nor to lose weight. In the resulting discussion the pharmacologic actions of the drug and its power to produce severe or fatal hyperpyrexia were explained and apparently understood.

About a month later, one of us (T.) was asked for advice on the treatment of this man, who was in the Central Emergency Hospital, with Dr. Charles Benninger in charge, from the effects of a dose of dinitrophenol taken that day. He died, however, before the suggested cold bath and oxygen therapy could be started.

On admission to the hospital at 5:30 p. m., he told the attendants that one week previously he had taken a single 5 grain dose of dinitrophenol by mouth and that he had suffered a terrific fever for about half a day, with a loss of weight of 6 pounds (2,737 Gm). Wishing to repeat the treatment, he said he took another 5 grain dose by mouth at 11 a. m. on the day of admission. At 5 p. m. he was taken to the Emergency Hospital suffering from hyperpnea and pain in the chest. At 7 o'clock the rectal temperature was 105.0 F., and at 9:30 105.7 F. The blood pressure was 140 systolic and 124 (?) diastolic, with a rapid pulse up to 146 per minute. Respiration was extremely rapid and deep. Treatment by the hospital staff consisted of two doses of morphine, one-fourth grain (0.016 Gm), for the chest pain and acetylsalicylic acid, 20 grains (1.3 Gm), for the fever. There was some restlessness and mental confusion beginning about 9 p. m., and death occurred at 10 o'clock. Twenty minutes later the rectal temperature was above the limits of the clinical thermometer (probably around 115 F.), rigor was present, and the skin appeared darkly cyanotic.

Examination of the patient's belongings by the authorities showed a box of sodium dinitrophenol capsules, of 100 mg each, with only ten of the original hundred capsules left. Since he took the drug only twice, he must have taken ninety capsules, or 9 Gm. of the drug, in these two doses, or at least 4.5 Gm. in the final dose, which proved fatal.

Subsequent investigation revealed that he was receiving trypanamide injections from another physician, which he had requested for syphilis of the central nervous system. The blood Wassermann reaction was negative but he had insisted on being given the antisyphilitic therapy that would not permit a spinal fluid examination. He had also been interested in the possible use of fever therapy, such as by malaria or diathermy, in the treatment of the supposed syphilis.

From the evidence available, we cannot be sure whether he took 5 Gm. by mistake for 5 grains, as might be inferred from his statement about dosage, or whether he took a large dose deliberately, for the therapeutic effect of the high fever he knew it would produce. The latter seems the more probable explanation, since, in a conversation with a physician during the week after his first dose, he described his first experience with it as being accompanied by a very high fever, which was very beneficial. On being urged by the physician not to be so reckless again, he retorted that he would take another dose the next Sunday and that, if it resulted fatally, he would be just another martyr to science.

Necropsy—This was performed at the San Francisco coroner's office eleven and a half hours after death. We are indebted to Dr. Sherman Leland, autopsy surgeon at the coroner's office, for permission to witness the autopsy and for the tissues given to us for microscopic study.

The body was that of a well developed, well nourished man of medium stature who appeared to be about 50 years of age. Mixed grayish brown hair was present over the scalp. The skin was of fine texture throughout and showed a barely perceptible yellowish tint. The subicteric tint was most apparent in the sclerae and conjunctivae. A marked postmortem lividity of the dependent parts was present.

The thorax and abdomen were covered by a moderate layer of yellow subcutaneous fat measuring 3 cm. in thickness. The abdominal and thoracic muscles were of normal color and appearance. The peritoneum was smooth, moist and glistening. A moderate amount of fat was contained in the long apron-like omentum. The stomach was moderately distended, extending 2 inches below the left costal margin. Considerable gas and semisolid fecal material were retained in the colon.

A number of fibrous adhesions were scattered throughout the left pleural cavity. Both pleural cavities were free of fluid.

A large amount of fat was present in the anterior mediastinum. The pericardial sac contained a few cubic centimeters

of clear, straw-colored fluid. A few small ecchymotic hemorrhages were present in both visceral and parietal layers of the pericardium.

The heart was of normal size. A moderate amount of sub-epicardial fat was present over the right ventricle. The heart valves and chambers were normal. The heart muscle was a medium reddish brown, firm and rather moist. The endocardium was glistening and showed a moderate edema. Occasional small hemorrhagic spots were also present in the endocardium. The base of the aorta was essentially normal.

The left lung was about normal size and heavy, and on cut section it showed a marked congestion and a moderate pulmonary edema. The surface was a purplish red. The bronchi were congested and contained a small amount of bloody mucus. No frothy fluid, however, was present in the trachea or large bronchi. The peribronchial lymph nodes were small and anthracotic.

The right lung showed an old apical scar. Otherwise the lung was essentially the same as the left.

The spleen was of normal size. A few fibrous adhesions were present over the convexity. The cut section showed a dark congested pulp of firm consistency.

The left and right kidneys were of normal size, showing slight remnants of fetal lobulation. The capsules stripped readily. The surfaces were smooth and of a medium reddish brown. On cut section the parenchyma appeared normal. The peripelvic fat was moderately increased in amount. The mucosa of the renal pelvis was smooth, pale and glistening.

The liver was of normal size. The capsule was smooth, except for a few tiny areas in which it appeared slightly "loose." Cut section showed a moderate degree of congestion and a slight but definite icteric tint. The liver cut with normal resistance.

Pale golden yellow bile of normal viscosity was contained in the gallbladder. The latter was of normal size. Considerable fluid of a pale yellow was present in the stomach. The color

Fig. 1—Moderate congestion and slight detachment of liver cells. Slightly reduced from a photomicrograph with a magnification of 80 diameters.

appeared to be due to bile staining and was not the typical color of dinitrophenol.

The calvarium was of normal thickness and markings. The brain showed a definite but slight edema. A few tiny hemorrhagic spots were present in the pia over the temporal and parietal lobes.

The anatomic diagnosis was dinitrophenol poisoning fatal, ecchymoses of the endocardium, pericardium and pia, pulmonary edema, tuberculosis, pulmonary and apical, healed, and pleuritic adhesions.

Histologic examination of the liver showed a slight detachment of the hepatic cells from one another (figs 1 and 2) with no apparent change in the reticulo endothelial cells. A slight fatty infiltration was present in the periphery of the lobules.

An extreme congestion of the lung was present throughout. The septums and the alveolar walls showed a marked congestion and a slight edema. Small amounts of plasma with a few red blood corpuscles were present in some of the alveoli.

Fig. 2—Detail of detachment of hepatic cells. Slightly reduced from a photomicrograph with a magnification of 450 diameters.

(fig 3). In a few sections, some of the small blood vessels were filled with masses of agglutinated red blood corpuscles.

Sections of the heart showed considerable transverse fragmentation of the muscle fibers and a slight variation in the intensity of staining.

Histologically, the kidney showed a moderate congestion of both cortical and medullary portions in some areas. The glomeruli were essentially normal aside from congestion. In scattered areas, some of the convoluted tubules showed a slight to marked cloudy swelling of the lining epithelium with beginning detachment of the lining cells.

The brain sections showed no evident abnormalities and no evidence of syphilis.

Aside from a moderate congestion of the pulp, the spleen was essentially normal.

Estimation of Dinitrophenol in the Blood—The blood was partly hemolyzed so that a clear plasma could not be obtained. With the use of blood to which dinitrophenol had been added as a standard for comparison the content of dinitrophenol was estimated colorimetrically, by two different methods, as follows.

First method. Blood was diluted ten times with distilled water, a protein-free filtrate was obtained with sodium tungstate and sulphuric acid. Clear colorless filtrate was alkalinized with sodium carbonate and the color estimated against the standards made at the same time in normal blood. Five cubic centimeters of the patient's blood was found to contain 0.15 mg of dinitrophenol. For a total blood volume of 10 per cent of his estimated body weight of 80 Kg. this would give 240 mg in the blood. Or, if evenly distributed between blood and tissues it would indicate about 24 Gm of dinitrophenol in the entire body.

Second method. A 10 per cent solution of the patient's blood in distilled water and standard solutions of dinitrophenol in blood were acidified and extracted with chloroform, the chloroform was removed and the residue evaporated to dryness over a water bath. The residue was taken up in water with sodium carbonate, reacidified and extracted with chloroform.

The chloroform was evaporated off again and the residue redissolved with sodium carbonate and distilled water up to volume. With the use of Wilpole's double tube technique, against control tubes treated similarly, 5 cc of the patient's blood was found to contain 0.19 mg of dinitrophenol. This would give, calculated as before, 304 mg in the blood, or 304 Gm of dinitrophenol in the whole body. The average of these two results would be 272 Gm of the acid dinitrophenol, or 3.31 Gm of the sodium salt which he actually took.

We know from experiments now under way that dinitrophenol is rapidly excreted in the urine, the greater part leaving the body within twenty-four hours. Since the patient survived the administration eleven hours, during which time excretion was doubtless going on, the amounts of dinitrophenol demonstrated in the blood are in general agreement with the aforementioned conclusion, namely, that about 5 Gm was the dose actually taken. Since the average daily clinical dose is 300 mg of sodium dinitrophenol, he took what was probably about seventeen times the usual therapeutic dose and about eight times the highest dose we have ever given to the most resistant patients.

SUMMARY

1 A case is reported of death occurring eleven hours following the oral administration of between eight and seventeen times the usual therapeutic dose of dinitrophenol.

2 The dosage taken was estimated, by various methods, to have been at least 24 but more probably 5 Gm. The man weighed approximately 80 Kg, giving an estimated dosage of 62.5 mg of dinitrophenol per kilogram of body weight.

Fig 3—Marked congestion of alveolar and septal blood cells. Slightly reduced from a photomicrograph with a magnification of 80 diameters.

3 The drug was self-administered with the apparent attempt to produce hyperpyrexia as a therapeutic measure for a supposed syphilis of the central nervous system.

4 The rectal temperature shortly after death was so high that it could not be recorded by a clinical thermometer, probably being at least 115 F.

5 The onset of rigor mortis was rapid, the body being rigid within ten minutes.

6 A subicteric discoloration of the sclerae and conjunctivae was present and was due in all probability to the color of the drug itself.

7 The anatomic changes consisted chiefly in a marked rigor mortis, an acute pulmonary congestion and edema, ecchymotic hemorrhages in the endocardium, pericardium and pia, mild nephrotic changes in the kidneys, and a slight detachment of the liver cells from one another.

8 The clinical and anatomic changes bear a striking resemblance to those seen in cases of heat stroke.

Clinical Notes, Suggestions and New Instruments

TRANSDUODENAL DECOMPRESSION AND REINTRODUCTION BY PROTOCYLIS OF GASTROINTESTINAL DRAINAGE IN ACUTE MECHANICAL ILEUS

CARL G. ROBERTS, M.D., Chicago

Mrs. F. B., aged 45, married and the mother of two children, admitted to St. Elizabeth Hospital, July 23, 1933, had three days previously had a sudden onset of colicky pain in the epigastrium, which localized in the right lower quadrant within twenty-four hours. Simultaneously with the onset of pain she vomited repeatedly and felt as if she had a fever. After three days of ineffectual self-medication, a physician was called, who advised immediate removal to the hospital.

Her previous history was essentially negative with the exception of an attack of scarlet fever in infancy and a fracture of the right seventh rib due to an automobile accident in January 1933. The family history revealed that one sister had died of pulmonary tuberculosis.

On admission her temperature was 100 F, pulse 104 and respiration rate 28. There was marked rigidity of the right abdominal muscles with pronounced tenderness at McBurney's point. The leukocytes numbered 16,800, with 90 per cent polymorphonuclears, 5 per cent lymphocytes and 5 per cent large mononuclears. The urine contained a trace of albumin, many hyaline casts, a number of epithelial cells and a few pus cells.

The general appearance of the patient was indicative of a condition more serious than was suggested by her pulse and temperature. A tentative diagnosis was made of acute appendicitis with probable rupture.

Examination through a McBurney incision disclosed a perforated gangrenous appendix, very black throughout its length, surrounded by about 180 cc of greenish yellow, foul smelling pus. The adjacent cecal wall was edematous, discolored and congested. The appendix was removed, the pus was evacuated, and Penrose drains were placed in the paracolic fossa and pelvic basin. The muscle, fascia and skin were left unsutured, the entire operation consuming twenty-five minutes.

The pathologic examination, by Ernst Pribram, July 25, revealed that the appendix was 3 inches (7.6 cm) long and about one-half inch (1.25 cm) wide. The wall was thick and green throughout. The mucous membrane was necrotic. The periappendiceal tissue, 1½ inches (3.75 cm) in diameter, was intensely infiltrated and inflamed. Microscopic examination revealed gangrenous appendicitis and perityphilitis. A smear from the abdominal wall showed pus cells yielding gram-positive and gram-negative bacteria and diplococci.

After the first two days the patient's pulse rate varied from 88 to 100, but she continued to have a septic temperature. Drainage was profuse, both smear and culture showing many gram-positive and gram-negative diplococci and bacteria.

August 3 she had a severe chill lasting twenty-five minutes followed by a temperature of 102 F and a pulse rate of 138. During the next twenty-four hours she was unable to void urine and repeated catheterization was necessary. August 7,

bimanual examination revealed bulging of the culdesac, and through a posterior colpotomy 500 cc of pus was evacuated. Following this, the temperature was distinctly lower for two days, when it again became irregularly septic. Voluntary micturition reappeared after the operation, accompanied by diarrhea, which continued for a few days.

August 11, a roentgenogram revealed marked elevation of the right diaphragm with a limitation of movement, and, although no fluid level was apparent, this finding together with the persistent septic temperature was suggestive of subphrenic abscess. August 12, she was again removed to the operating room, the ninth rib was resected in the midaxillary line and the subphrenic space was entered by the transpleural route, where an abscess was found and drained.

The temperature and pulse rate gradually returned to normal, so that by August 21 they were 98.8 F and 80, respectively. The general condition of the patient, however, was not entirely satisfactory, as the primary abdominal wound showed little tendency to heal, still draining very profusely. September 13, a blood transfusion was given to combat the severe sepsis and anemia, following which her condition improved, drainage decreased and both wounds began to heal.

October 11, she complained of cramplike pains and vomited a number of times. An enema resulted in the evacuation of a

corresponding decrease in nonprotein nitrogen and carbon dioxide combining power, the pulse rate returned to normal, and on October 16 a glycerin enema resulted in the expulsion of much flatus and a large stool. The patient was given increasing quantities of liquids, and on October 22 she was able to sit out of bed.

Because of her previous operation and prolonged drainage, it was felt that the obstruction was due to adhesions involving only a part of the circumference of the intestinal wall, therefore the chances were good for spontaneous recovery of peristaltic function if distention was relieved and the morgeanic salts were replaced. This conjecture proved correct, the convalescence was uneventful, no secondary operation was necessary, and the patient was dismissed, November 5.

REINTRODUCTION OF GASTRIC CONTENTS

After reading the case report of Block¹ of Philadelphia, who reintroduced the gastric contents by rectum in a case of acute dilatation of the stomach, I felt that this might be a desirable method of replacing the lost gastric and intestinal fluids in certain cases of obstructed ileus.

In the case reported by Block¹ the use of the acid gastric secretion resulted in irritation and diarrhea but the results otherwise were gratifying. In the duodenal contents, however,

Fig 1—Elevation of right diaphragm indicating presence of subphrenic abscess. Aug 11, 1933.

Fig 2—Appearance Oct 11, 1933, showing Levine tube in duodenum and distended, gas-filled loops of ileum arranged in vertical instead of transverse ladder formation.

Fig 3—Barium enema showing point of obstruction near ileocecal valve. End of tube is seen below transverse colon.

formed stool but no flatus. Nausea and vomiting increased, however, not even water being retained. On examination there was slight abdominal distention, borborygmi, visible peristaltic waves and tenderness in the umbilical and hypogastric regions. A working diagnosis of acute ileus was made, following which a flat roentgenogram revealed gas-filled loops of ileum and a barium enema disclosed a point of obstruction proximal to the ileocecal valve.

Although the diagnosis was made within twenty-four hours of the onset, the patient's condition was so grave that it was deemed unwise to attempt even an enterostomy. The stomach was lavaged and a Levine tube passed intranasally through the stomach into the second portion of the duodenum. It was felt that, in the absence of segmentation of the bowel and a generalizing peritonitis, this would result in decompression, just as an enterostomy relieves distention. There was no further vomiting following the passing of this tube which remained in situ for three days. The drainage material, composed of gastric, biliary, pancreatic and jejunal fluids, was collected from the tube and given to the patient by proctoclisis in quantities of 180 cc every four hours. Hartmann's solution and dextrose were used intravenously, together with one ampoule of pitressin every three hours.

There was immediate improvement in the general condition of the patient, within forty-eight hours the pain and distention disappeared, there was an increase in blood chlorides with a

the acid gastric juice is neutralized by biliary and pancreatic secretions, so that the collected fluids are alkaline in reaction and are not irritating to the normal rectal mucosa.

What of the danger from toxicity of this material? According to Elman,² a liter of normal intestinal contents containing trypsin, peptones, phenols, amines and other substances together with gas bacilli may be reintroduced in the normal gastrointestinal tract without any harmful results. A few cubic centimeters of some normal intestinal contents are sufficient to kill when injected in the circulation. The toxin present in intestinal obstruction does not seem to be harmful in the presence of undamaged mucosa, retaining its normal power of selective absorption,³ therefore when reintroduced by proctoclisis not only is the drainage material harmless but its composition is probably superior and more adaptable than any synthetic solution that can be devised. The experience of Wilkie⁴ is strongly corroborative of this statement.

The question of the absorptive ability of the rectum may be raised, but, in the presence of depletion of body fluid or dehy-

dration with its consequent increase of blood concentration and viscosity, absorptive capacity is increased. Perusse⁵ demonstrated that isotonicity is not the ideal concentration for proctoclysters, as a hypotonic solution is more readily absorbed. Dehydration secondary to the vomiting of ileus increases the blood concentration, consequently a solution even more concentrated than the gastro intestinal fluids will be readily absorbed if given by proctoclysis.

This case is reported with the full realization that nothing can be more misleading than to base positive opinion on one or more cases without extensive scientific observation checked by proper controls. Further investigation should be based on scientific experimental research, amplified by clinical application over a considerable period of time, before logical conclusions can be reached. The results obtained in this one case were so dramatic and positive that the report seems warranted as a clinical experience, which may be an inspiration for detailed investigation and experimental research to test its merit.

152 West Division Street

THE LINGUAL TONSILS AND SOME OF THEIR COMMON ABNORMALITIES

LESTER HOLLANDER, M.D. PITTSBURGH

Maximow,¹ in his textbook on histology, gives a clear-cut description and three excellent illustrations of the lingual tonsils. He says "The bulgings on the root of the tongue are caused by spherical accumulations of lymphoid tissue, they are peripheral nodules with germinal centers—the lingual tonsils and the follicles of the tongue. On the free surface of each of them a small opening can be noticed. It leads into a deep, irregular invagination lined with stratified squamous epithelium—the crypt. The epithelium of the crypt is surrounded by lymphoid tissue, innumerable lymphocytes infiltrate the epithelium and assemble in the lumen of the crypt, where they degenerate and form masses of detritus with desquamated epithelial cells and bacteria. The excretory ducts of the follicles open into the crypt or on the free surface."

The importance of the lingual tonsils arises from the fact that a considerable number of the medical profession is not mindful of their existence and also that some of the abnormalities which occur in them are not sufficiently familiar. Although they may be involved in any one of what Boyd² calls the "big four" of pathologic changes of the tongue—syphilis, carcinoma, tuberculosis and inflammation—they are much more frequently the seat of simple hypertrophy, residual infection or hyperkeratosis of the epidermis overlying them.

These simple conditions are frequently viewed with great alarm, as they are interpreted as malignant disease. Attention is usually called to them during routine examination of the throat or mouth. Subjective symptoms occur infrequently and only when they are the seat of residual infection. Occasionally patients who are in the habit of looking at their tongues become aware of their presence and become greatly alarmed by finding these lesser or greater lumps.

I have made it a point to observe them for some time on routine examinations of the tongue. Mostly they protrude but slightly from the margin of the organ at the root; the opening of the crypt is small under normal conditions. As they are part of the lymphoid structure of the body, they are not infrequently found enlarged in patients in whom generalized lymphoid hypertrophy occurs.

Dissimilarity in size or an increase in the aperture of the cryptic opening, which may become deep and fissure-like, calls for careful examination. In the latter instance it is not infrequent to find that a semisolid, cheesy material can be expressed from the crypt. In several instances I have noticed an offensive

odor associated with it. One such example is noteworthy to record because the patient's chief complaint was fetor ex ore. Only the left lingual tonsil was enlarged sufficiently to widen the crypt. Removal of the tonsil-bearing area of this side of the tongue improved the condition.

Subjective symptoms do occur in conjunction with residual or chronic infection. Especially is this true if the opening is insufficient to permit the easy outflow of the purulent material. At times this leads to fairly marked tenderness, the symptoms are usually exaggerated on mastication.

Three cases are presented briefly to illustrate some of the points in question.

CASE 1—W. L. F., a man, aged 36, was sent to me by a laryngologist with a diagnosis of early carcinoma of the tongue at the margin. Examination showed the right lingual tonsil somewhat larger than the left, but the crypt was not distended. The mucous membrane covering a portion of it showed a grayish white plaque about 1 mm in diameter, over which it seemed to be thickened. The rest of the mucous membrane covering the lingual tonsil looked macerated. There were no subjective

Fig. 1 (case 1)—Acanthosis overlying the mass of lymphoid structure underneath it.

symptoms. This abnormality was noticed during a routine throat examination. The entire tonsil-bearing area was removed by radio knife cautery.

Microscopic examination showed a normal lingual tonsil and hyperkeratosis of the epidermis overlying it. In figure 1 the slight acanthosis is shown overlying the mass of lymphoid structure underneath it.

CASE 2—Mrs. W. W., aged 42, presented herself for examination on account of pain and tenderness at the left side of the tongue. The left lingual tonsil was somewhat larger than the right and was firmer in consistency. The opening of the crypt was patulous or distended. The area was very sensitive. No roughness of the teeth was noted. The entire area was removed by radio knife cautery. Microscopic section showed, in addition to a fairly large lymphoid structure, the presence of inflammatory exudate about the periphery and intracellular edema. It was interpreted as a chronic (residual) infection of the lingual tonsil.

CASE 3—Mrs. G. B., aged 48, was referred to me because of a bilateral enlargement at the root of the tongue. The medical history was interesting because of a frequently recurring tonsillitis which she had suffered over a period of the last ten years.

Figures 2 and 3 demonstrate clearly what was found. On the right side a lobulated mass, soft but not friable, was pro-

AUTOMATIC HYPODERMIC SYRINGE FOR SELF ADMINISTRATION OF INSULIN AND OTHER USES

HERBERT BUSHER, M.D., ST. PAUL

The greatest drawback in the treatment of diabetes with insulin, encountered in active practice, is the necessity of the patient to administer this medication himself with a hypodermic needle. The instinct of self preservation creates in every human being a fear to inflict pain on himself. Many a sufferer from diabetes struggles along on diet, to his own detriment and to the chagrin of his physician simply because he lacks the will power necessary to overcome this natural inhibition.

To overcome this difficulty I have devised an automatic hypodermic syringe. The device holds the syringe under ten

Fig 2 (case 3)—Hypertrophy of the right lingual tonsil

culosis, irritation from a rough or jagged tooth and irritation from tobacco, especially if the latter is used in the form of chewing, are the foremost considerations. Without going into the minutiae of detail, in general the following points will lead one straight. The absence of (a) hardness, as in carcinoma; (b) progressive or retrogressive changing character as in a syphilitic gumma; (c) satellite lymph node enlargement as in

Fig 3 (case 3)—Hypertrophy of the left lingual tonsil, showing deep fissure like crypt

a chancre, (d) slow progressive ulceration quality, as in tuberculosis (unless the residual infection is due to the Koch bacillus).

If there is doubt, however, the tonsil-bearing area can be easily removed under local anesthesia. The radio knife cautery simplifies the procedure. A microscopic examination will then usually clear up the diagnosis.

SUMMARY

1 The three cases of lingual tonsils reported here illustrate certain common disorders found in them.

Fig 1—Automatic hypodermic syringe

Fig 2—Method of use

sion by means of a spring. After the syringe has been filled with the required amount of insulin it is drawn back and cocked. The device is then placed firmly against the skin, and by touching a trigger the needle is thrust through the skin with lightning rapidity, very much as the modern spring lancet punctures the lobe of the ear in obtaining a drop of blood for laboratory examination. The rapidity with which the needle is inserted precludes any distortion of the skin, and therefore makes the procedure practically painless. Also, the spring-power insertion eliminates the voluntary push with its attendant inhibitory fear.

In addition to self administration there are other uses for which this device is well adapted. For instance children will appreciate the painless injections not only in pediatric practice but also in the schools, where most of them receive their diphtheria immunizations.

The device has a foot-rest, which can be adjusted to the desired depth of needle insertion. The needle can readily be removed and another put on without unsterilizing it. And the syringe itself can easily be taken out of the device, and another syringe put in.

NEW APPARATUS FOR REHABILITATION FOLLOWING
INJURIES TO THE LOWER EXTREMITIES

G LYNN KRAUSE M D St Louis

The after-care of patients recovering from fractures of the lower extremities has always been a considerable problem both to the patient and to the physician. From the time that the patient is ready to bear his weight on the lower extremities until his discharge he is constantly apprehensive of falling and disturbing the healing of the fracture. In order to remove these fears from his mind and to restore self confidence in his power of locomotion, I have devised an apparatus that has proved successful in a number of cases.

CONSTRUCTION AND USE OF THE APPARATUS

The apparatus consists of a framework of galvanized iron pipe joined together by tees and elbows. The base of the frame is 25 by 25 inches and is mounted on ball bearing rubber tired casters. It can be opened in front and wheeled up to the patient and then fastened. The upper framework is smaller than the base, measuring 20 by 20 inches and 35 inches from top of base to floor. Three sides of the frame are rigid, the fourth, or front, consists of a movable piece of pipe, which locks into place by a spring catch. The side opposite to this gate, or the back of the frame, is curved so as to accommodate the patient's hips and buttocks. The sides, to the right and left, are equipped with arm supports similar to those on crutches, and can be raised or lowered by set screws to fit the patient and help him to support himself during the early part of his rehabilitation.

These crutch supports are in turn connected to the top framework by oversized tees, one on each side, which act as hinges so that the crutch attachments may be folded on to the lower frame when the patient has learned to support himself well enough to do away with the arm supports. From the center of the gate in front to the center of the curved bar in the rear, a well padded canvas sling is suspended. This strap passes between the patient's legs and supports the entire body above the hips. This arrangement allows the feet to touch the ground, so that the patient can begin to move his limbs in the normal manner for walking and yet keeps the weight of his entire body off the injured limb. As he recovers his confidence and the injury becomes more secure, the strap between his legs is gradually lowered so as to place more and more weight on his feet. The casters allow him to 'walk' about as he regains confidence and reeducates the muscles of his limbs. At first the patient uses the adjustable crutch supports under his arms, but, as he improves and bears more weight, these supports are folded to the sides. Since the base is wider than the top it is impossible for the apparatus to tip over. The adjustability of crutch and sling will accommodate any adult patient.

Fig 1—Ambulatory crutch for certain disabilities of the lower extremities

The apparatus is being used at present on a man, aged 54, weighing 228 pounds (103 Kg). Both legs were broken at the knee joint in an automobile accident, the fracture extending into the joint, the femur, tibia and fibia were broken. After a fair amount of bony union had been obtained, I was unable to get him to use crutches. When I put him in this device he was able in a few days to walk from one to two blocks. The exercise afforded is rapidly bringing back the use of his joints and muscles. He has acquired his equilibrium and confidence in walking. Also there is no danger of falling and injuring the broken parts or incurring any additional injuries.

With this apparatus the time the patient stays in bed is considerably shortened, which is a distinct advantage, particularly in elderly patients, in whom pneumonia is so prone to develop.

This apparatus can be used not only for fractures but also for rehabilitation in various forms of paralyses involving the lower extremities and in old cases of arthritis of the lower extremities, muscular dystrophies and atrophies, poliomyelitis, ankylosis and other conditions.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
H A CARTER Secretary

THE MCINTOSH ELECTRICAL CORPORATION AND THE AMERICAN COLLEGE OF PHYSICAL THERAPY

IN THE JOURNAL, Sept 23, 1933, page 999, the Council on Physical Therapy authorized publication of the report dealing with the American College of Physical Therapy, 5 North Wabash Avenue, Chicago. The purpose of this article was to inform the profession concerning the status of the so-called "College."

Several announcements of the "College" advertising the alleged postgraduate course and clinics in physical therapy were referred to the Council on Physical Therapy by physicians who had received them through the mail. In each case an announcement was attached to a piece of advertising matter of the McIntosh Electrical Corporation.

Two days after the aforementioned issue of THE JOURNAL was in print, a letter was received from the McIntosh Electrical Corporation by the secretary of the Council on Physical Therapy. In this letter the McIntosh Corporation definitely denied any present affiliation with the American College of Physical Therapy. The Council on Physical Therapy takes this opportunity to publish this statement of the McIntosh Electrical Corporation.

CIRCUMDUCTOR NOT ACCEPTABLE

The Circumductor is a mechanical exercising machine, manufactured by the Circumductor Corporation, Ltd., Los Angeles. The machine resembles an operating table equipped with extensions, levers, clamps and straps, to which the patient, lying on his back, may be fastened securely. Passive exercise is administered by means of various levers which are moved or rotated through certain predetermined angles by an electric

motor Arrangements are made also for so called stretching of the muscles

In the advertising matter propagandizing this unit, the firm makes this statement "The Circumductor positively accomplishes the following

- "a Equalization of tension of opposed sets of muscles
- "b Relief of muscular congestion
- "c Improvement of muscular tonus
- "d Rebuilding of weak and unexercised muscles
- "e Breaking down of muscular adhesions"

In the Council's investigation of the Circumductor, the promoters were requested to submit evidence to verify the therapeutic claims advanced After giving careful consideration to such evidence as was made available, the Council declared it insufficient to justify the acceptance of the machine Most of the reports received from those who have had experience with it were negative and, moreover, in noncritical reports recording optimistic views, only three or four cases were cited as evidence One user believed that the machine produced a certain psychologic effect on patients which effect he considered to have some value The Council is of the opinion that psychologic effects may be produced more economically and scientifically thru by a utlization of this machine

Because of the lack of conclusive and critical evidence to substantiate the therapeutic efficacy of the claims made and because the safety of the unit is questioned the Council decided to omit the Circumductor from its list of accepted physical therapy devices

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH Secretary

DEXTROSE (See New and Nonofficial Remedies, 1934 p 270)

The following dosage forms have been accepted

Sterile 2½% Dextrose in Physiological Sodium Chloride Solution in Vacoliter Container Each 100 cc contains dextrose U S P 2.62 Gm and sodium chloride 0.85 Gm

Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corp Chicago eastern distributor)

Sterile 5% Dextrose in Physiological Sodium Chloride Solution in Vacoliter Container Each 100 cc contains dextrose U S P 5.25 Gm and sodium chloride 0.85 Gm

Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corp Chicago eastern distributor)

Sterile 7½% Dextrose in Physiological Sodium Chloride Solution in Vacoliter Container Each 100 cc contains dextrose U S P 7.85 Gm and sodium chloride 0.85 Gm

Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corp Chicago eastern distributor)

Sterile 10% Dextrose in Physiological Sodium Chloride Solution in Vacoliter Container Each 100 cc contains dextrose U S P 10.50 Gm and sodium chloride 0.85 Gm

Prepared by Don Baxter Intravenous Products Corporation Chicago (American Hospital Supply Corp Chicago eastern distributor)

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT PAUL NICHOLAS LEECH Secretary

CYPRESS OIL-N N R AND OIL OF CYPRESS-SCHIMMEL AND CO OMITTED FROM N N R

Cypress Oil, with the accepted brand Oil of Cypress-Schimmel and Co (Fritzsche Bros, Inc, distributor), was first included in New and Nonofficial Remedies in 1912 as a palliative preparation for use in whooping cough With the expiration in 1933 of the current three year term of acceptance of the commercial preparation, the Council reviewed the evidence for the usefulness of the product The firm's submitted advertising consisted of a reprint of a paper by Dr O Soltman in Therapie der Gegenwart March, 1904 There appears to be little or no recognition of Cypress Oil in American or English

books of pharmacology There is brief mention of the drug in Pfundler and Schlossman's Handbuch der Kinderheilkunde.

In the light of these considerations the Council concluded that there is no good reason for the continued inclusion of Cypress Oil in New and Nonofficial Remedies and voted to omit it with the accepted brand

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

CURTISS BUTTERFINGER 1¢
CURTISS BUTTERFINGER SENIOR 5¢
THE CHOCOLATE COVERED PEANUT BUTTER CONFECTION

The Curtiss Candy Company, Chicago, submitted to the Committee on Foods Curtiss Butterfinger 1¢ and "Curtiss Butterfinger Senior 5¢" wrapped bar confections of chocolate coated centers prepared from peanut butter, corn syrup, sucrose, skim milk powder, molasses, salt, baking soda and flavoring

Manufacture—The center is prepared by cooking the corn syrup sucrose skim milk solids and molasses in a steam jacketed kettle until a definite temperature is reached The steam is turned off, the other ingredients are mixed in, the total mass is pulled and honeycombed by machine, and is mechanically spun to a desired size and shape The prepared centers are chocolate covered artificially cooled and wrapped.

Analysis (submitted by manufacturer) —		per cent
Moisture		20
Ash		12
Fat (acid hydrolysis method)		23.3
Protein (N x 6.25)		10.6
Reducing sugars as dextrose		14.0
Sucrose (copper reduction method)		25.3
Crude fiber		0.4
Carbohydrates other than crude fiber (by difference)		62.5

Calories—5 per gram 142 per ounce

Discussion of Name—The name Butterfinger for a food article suggests the presence of butter as an important ingredient In fact the product contains no butter but peanut butter or ground peanuts Foods containing butter and peanut butter respectively have greatly different nutritional values The term butter used as a part of the trade name for a food article containing no butter is misinformative and misleading Food names should be appropriate and conform to the nature of the foods "Peanutbutter Finger" accompanied by some such descriptive statement as "Chocolate covered peanutbutter confection" is an appropriate name and designation for this product

The manufacturer was informed of the Committee's criticisms and recommendations but has not demonstrated compliance This product will therefore not be listed among the Committee's accepted foods

NOT ACCEPTABLE

BA-BEE NON-ACIDITY BREAD

The Ba-Bee Pastry Shoppe, Erie Pa, submitted to the Committee on Foods a white bread called both "Ba-Bee Non-Acidity Bread" and "Ba-Bee Acidity Bread," made by the straight dough method having the following ingredients patent flour, buttermilk, water, yeast, salt dry skim milk, honey, cream of tartar, bicarbonate of soda and distilled vinegar (acetic acid)

Analysis (submitted by manufacturer) —		per cent
Moisture		40.0
Ash		1.6
Fat (ether extraction method)		2.0
Protein (N x 6.25)		10.9
Crude fiber		0.5
Carbohydrates other than crude fiber (by difference)		45.0
Acidity as lactic acid		0.73

Discussion—The submission to the Committee named the bread "Non-Acidity Bread" a leaflet accompanying the loaf designated the product "Acidity Bread" and stated "A White

Loaf produced under a new and scientific process This bread will not increase weight or create acidity in the stomach, as it does not contain any sugar or fat solids Try a loaf of this marvelous bread today

The submission discloses that the bread is prepared in the usual manner and not by a "new and scientific process" The bread will "increase weight" and "create acidity" in the stomach just as do other breads The claim the bread "does not contain any sugar or fat solids" apparently is intended to differentiate this bread incorrectly from other breads and thereby give greater plausibility to the absurd names and other false claims There is no objection to appropriate quantities of fat and sugar in bread

The bread names and advertising are deceptive, an attempt to convey fictitious quasimedical values to an ordinary food This product therefore, will not be listed among the Committee's accepted foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

RAYMOND HERTWIG Secretary

KREEMEX BUCKWHEAT AND WHEAT FLOUR

Manufacturer—Allied Mills, Inc., Kreemex Cereal Division, Greenville Ohio

Description—Self-rising flour mix containing buckwheat flour, standard patent flour, soya flour, dextrose, calcium acid phosphate, sodium bicarbonate, salt, corn flour and corn starch

Manufacture—Definite proportions of the formula ingredients are automatically mixed and packed in cartons

SATURDAY, APRIL 7, 1934

DINITROPHENOL POISONING

In this issue of THE JOURNAL appear the reports of two cases of sudden death from poisoning with dinitrophenol (pp 1141 and 1147). The authors review the available literature on the subject which would seem to indicate that the drug is treacherous and that its administration, as has been previously emphasized in THE JOURNAL, should invariably be under the control of a physician. In the case reported by Drs. Poole and Hanning a young woman secured for herself and took without medical instruction a dosage of this substance far beyond what has been established as a safe amount. In accordance with instructions placed on the label by the druggist from whom the preparation was purchased, the patient took 3 grams the first day, 6 grams the second day, 9 grams the third day, 12 grams on the fourth day, 12 grams on the fifth day, and possibly 6 grams on the sixth day. On the seventh day she died. Apparently an ordinary daily dosage of from 3 to 5 mg per kilogram of body weight is a safe therapeutic dosage. The patient began with a daily dosage of 180 mg and on the fifth day was taking 720 mg. Nevertheless, even these tremendous and obviously excessive doses were below the limit of what was thought to be the fatal dosage, based on animal experiments.

The investigators conclude that, as compared with animals, human beings have a more variable and an unpredictable susceptibility to dinitrophenol. While the literature on the subject, as far as concerns the use of this product on human beings, is not extensive, there is already evidence to indicate that the special susceptibility to the drug is far more frequent than drug sensitivity as applied to most other medical preparations.

As is usual with any drug used for cosmetic purposes, commercial interests have promptly entered the field of exploitation of dinitrophenol. There is not the slightest doubt that vast numbers of people are taking this preparation both with and without the advice of their physicians. At least two of the physicians who broadcast health information to the public

through the radio and through the press have mentioned the use of this drug and have apparently failed to warn the public adequately concerning its dangers. Innumerable letters have poured into the headquarters of the American Medical Association asking for further information. Reports such as those here referred to should be taken as a definite warning of the toxicity and the special danger associated with dinitrophenol in some cases. Physicians who administer the drug to their patients should inform them thoroughly concerning such dangerous manifestations as increased temperature, severe urticaria and pruritus, and recommend immediate discontinuance of the preparation on the appearance of any symptoms of this character.

LOBAR PNEUMONIA

Knowledge of the pathogenesis of lobar pneumonia has reached a point that offers unusually promising angles for continued attack. That these possibilities are not being neglected is attested by three recent articles emphasizing different phases of the problem. Moreover, wide dissemination of the advances in knowledge of pneumonia are necessary, since most practitioners see relatively few cases during the course of a year. Thus Sutcliffe and Finland¹ state that the number of cases of lobar pneumonia reported annually in Massachusetts is from 4,080 to 5,544, making perhaps one case a year for each of 6,595 practicing physicians.

Smillie and Leeder² investigating the spread of pneumonia have studied this problem by taking cultures of the nasopharynx in 264 contacts of 64 patients with lobar pneumonia due to types I and II pneumococci. The results indicate that about 20 per cent of the immediate family contacts of the patients harbored the homologous strain of pneumococci. Hospital contacts were rarely infected, however, and the Boston investigators therefore believe that it is justifiable to treat cases due to types I and II in open wards of general hospitals. The evidence studied suggests that there is some additional factor other than simple contact which determines the transfer of type I or II pneumococci from a patient with lobar pneumonia to contacts. Possibly colds may be the factor, or one of the factors, responsible. It was apparent that carriers of types I and II pneumococci may continue as carriers for a considerable period without giving rise to pneumonia in either the carrier or his contacts and without producing a second group of carriers.

Much stress has been placed on the early diagnosis of lobar pneumonia especially since the advent of specific serum therapy. With a view to improving the ability to make early diagnoses and follow the course

¹ Sutcliffe W. D. and Finland Maxwell. Type I Pneumococcal Infections with Especial Reference to Specific Serum Treatment. New England J. Med. 210: 237 (Feb.) 1934.
² Smillie W. G. and Leeder F. S. Epidemiology of Lobar Pneumonia. Am. J. Pub. Health 25: 129 (Feb.) 1934.

of the infection, Graeser, Wu and Robertson³ studied forty cases of lobar pneumonia by means of serial daily roentgenograms and physical examinations. Comparison between these methods showed the roentgenogram to be the superior in detecting the early lesion and disclosing the extent of the process while the consolidation was developing. At the stage of maximum consolidation, however, the two methods were about equally informative. Visceral displacement could not usually be demonstrated by physical examination. When seen in the roentgenogram it was generally manifested as an elevation of the diaphragm on the affected side. In a few cases a slight shift of the mediastinum toward the lesion could be shown.

Type specific serum has found its greatest usefulness so far in lobar pneumonia due to the type I pneumococcus. Sutliff and Finland in studying this matter further, find no room for doubt that concentrated type I antipneumococcus serum exerts a striking symptomatic effect and reduces the death rate by one half in type I lobar pneumonia in adults. They consider that the results which may be expected in patients treated before the end of ninety-six hours of illness are symptomatic change in two thirds of the recovered patients within thirty-six hours of beginning treatment, and a death rate of approximately 10 per cent. Again early diagnosis and prompt serum administration are emphasized. The high cost of potent serum, they consider, is a problem being gradually met by increased use and improvements in manufacture and distribution. In any case, the results are so valuable that the serum should be used regardless of cost.

SOME FACTORS IN WOUND HEALING

The rapidly growing knowledge of the manifold types of nutritional defects and their relation to human well being is beginning to influence almost every field of medical practice. Indeed, at present the investigation of the indispensable exogenous facts, such as the vitamins and certain inorganic compounds, and researches on the endogenous hormones, seem to vie with one another for consideration in the domain of practical therapy. Foods have become in the eyes of practitioners something more than mere carriers of energy. Glandular secretions and extracts, derived from tissues and organs distributed along the way from the pituitary to the gonads, are finding applications and experimental trial in a dozen unusual ways. As a medical writer remarked nearly a century ago, we have to cultivate a science and exercise an art.¹

Much is being written about "growth promoters," an expression used most commonly to include some of the vitamins, but any essential ingredient of the diet is in truth a "growth promoter," for without it the

normal development of a part or all of the organism is likely to be disturbed. From this standpoint, shortage of iodine or calcium or some unsaturated fatty acid (as has lately been contended) may be quite as disastrous as is the lack of one of the newly recognized vitamins. In the case of calcium or phosphorus, the presumable damage to developing teeth and their bony sockets is obvious to the dentist. The lack of iodine upsets the function of the thyroid gland and thus in turn the metabolism as a whole.

In many respects the processes of wound healing are comparable to those of growth. New tissue must sometimes be formed. Hence it becomes important to discover whether and, if so, in what respects repair processes in the body may be accelerated by special dietary measures. As recently stated,² malnourished patients must occasionally be subjected to surgical procedures, and often it is necessary to restrict the amount of diet after operation. Only too frequently does one observe the wounds of undernourished patients, particularly those of children, healing slowly and becoming infected. Unfortunately, it is not always possible in the clinic to establish the exact nature of a case of malnutrition or to determine the deficiency of the previous diet that produced it. So, too, it is quite impossible to tell whether a prolonged healing time of a wound is the result of malnutrition alone or of other causes more obscure.

For the present, these uncertainties can best be solved by recourse to animal experimentation. The studies of Harvey and his collaborators² are a step toward some of the solutions. They have shown that the rate of fibroplasia in "standardized wounds" of soft tissues notably in the stomach wall, is surprisingly independent of the diet. In adult animals, for example, the rate of return of healing strength in wounds of the stomach was not appreciably affected by complete starvation, nor was it affected by giving half the required amount of an adequate diet over a short period. On the other hand, the healing of wounds in the stomachs of young rats was decidedly retarded by giving only half the required amount of an adequate diet. This retardation in healing of the wounds in the stomachs of young rats can possibly be explained by a reduction either separately or in combination of certain elements of the diet. The most probable elements are the vitamins, especially in relation to the deficiency of proteins and salts.

It is satisfying to learn the remarkable ability of wounds to heal in spite of great variations in the amount of food consumed. Evidently, under stress the body mobilizes its reserves in an effective way regardless of the intake. Perhaps this circumstance will help to explain the recent observation³ that even marked interference with the circulation in the limbs need not retard the healing of fractures or other defects.

Current Comment

INSURANCE PRACTICE ITS QUALITY AND ITS ECONOMICS

American physicians have become accustomed to seeing the effects of compulsory health insurance depicted in a roseate hue. Representatives of the foundations who would lure the American medical profession into greater and greater participation in the trend toward socialistic and state medical practice are wont to emphasize the increased emoluments of the medical profession under such systems. Insidiously they urge that the vast majority of physicians are not adequately paid for the service they render and that compulsory health insurance or some similar system will greatly enhance the incomes of medical men. In this connection the following quotation from the *London Lancet*¹ provides both information and argument.

The deputation from the Insurance Acts Committee was received by the Minister of Health on March 8th when Dr. Dain spoke of the hardship inflicted on many members of the profession by the 10 per cent cut on the 9s capitation fee. This hardship is common knowledge amongst medical administrators although hardly realised by the public. Many insurance doctors have had to take their sons away from public schools as a result of this and other deductions. The quarterly cheque without the cut was often completely mortgaged before its arrival, ends hardly met then, so that the loss of ten pounds out of every hundred just made the difference, necessitating change of plans of outlook, and often of environment. The national emergency which docked panel cheques also affected private practice. The patient who used to consult his doctor when not well learnt to go without medical attendance, others who used to be regular private patients went to hospitals, with the result that the receipts from private practice have fallen considerably in every area, and particularly in those industrial areas where unemployment is severe. The increasing number of doctors in private practice has made things still more difficult.

The Minister could not promise the deputation that the cut would be removed, but he did promise that the profession would not be forgotten and that their 10 per cent should be restored if other people's were restored. This was really confirming the promise made by Mr. Neville Chamberlain when he was Minister of Health at the time the cut was imposed—namely, that as the profession had faced the situation created by the national emergency with such good grace he would see to it that when the emergency was over the capitation fee should be restored to normal at the earliest possible moment.

Turning from this enlightening paragraph, one finds another interesting point of view expressed in a discussion by Dr. Hugh Cabot² before the Association of American Medical Colleges. The proponents of state systems of practice have constantly asserted that the people generally in the countries in which such systems prevail get more and better medical service than is available to the majority of the American people. Dr. Hugh Cabot has at various times in his addresses before medical organizations expressed a highly social point of view. Nevertheless, his personal observation of medical practice is definitely in favor of the American system. Thus he says:

A brief and cursory and, I think perhaps careless study of the situation in five or six foreign countries in which my person and family have been involved has convinced me that there is no country in the world at the present time, unless it

be England, in which the average American can receive the grade of medical attention which he has come to believe necessary. In other words, the medical service in many other countries is very well suited to the demands of those countries. I think, for instance, that Denmark is, perhaps, the outstanding country in which the people and the medical profession are very well adjusted to each other, but I am not at all prepared to assume that if we should transfer the precise conditions in Denmark to this country that anybody who properly represented the public would be satisfied with it.

WILLIAM H. WELCH—TWO ANNIVERSARIES

On April 7, Dr. William H. Welch completes fifty years of continuous service to the Johns Hopkins University and to the Johns Hopkins Hospital, on April 8, he celebrates his eighty-fourth birthday. *THE JOURNAL* wishes to extend to Dr. Welch on this occasion its congratulations both on reaching this birthday and on his continuous interest in the problems of American medicine, from both the scientific and the social point of view. It is hoped that the coming years may give opportunity for a continuance of his earnest and sincere counsel.

SPECIES DIFFERENCES IN ORGANO- THERAPY FOR PERNICIOUS ANEMIA

It has long been known that, in addition to the hematologic and neurologic symptoms of pernicious anemia, the syndrome is characterized by gastric involvement. Indeed, it has been said¹ that achlorhydria is the usual accompaniment of the disease. The marked efficacy of beef, hog and horse liver as well as of desiccated whole stomach of the hog indicates that these tissues contain something which takes an important part in hemopoiesis but which, in the absence of normal gastric function, cannot be obtained from ordinary food materials. That this curative property does not reside in liver and stomach tissues of all species is apparent from some recent studies on the dog. Ivy, Morgan and Farrell² have demonstrated that total gastrectomy in this species is not regularly followed by anemia. In later studies³ in which canine liver was used, the response with both the extract and the whole tissue led to the conclusion that, although the substance effective in pernicious anemia is present in dog's liver the concentration there is only about one-fifth that in the livers of the other species commonly used in this connection. Likewise, when desiccated whole stomach of the dog was given to patients with pernicious anemia there failed to appear the typical signs of remission of the disease, despite the fact that all these persons responded in the usual way to the administration of horse liver. As total gastrectomy in the hog gives rise to an anemia⁴ and hog liver is a potent therapeutic agent in pernicious anemia, it appears that gastric function in the dog does not play the same part in hemopoiesis that it does in certain other species.

Association News

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast to coast network each Monday afternoon from 4 to 4 15 Central standard time (5 o'clock Eastern standard time, 3 o'clock Mountain standard time, and 2 o'clock Pacific standard time)

The next three broadcasts will be as follows

April 9 Peculiar Accidents, W W Bauer, M D
April 16 Bird with a White Breast, W W Bauer, M D
April 23 Sanitation Goes Modern, W W Bauer, M D

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45 Central standard time. The next three broadcasts will be as follows

April 12 Pretty Polly, W W Bauer, M D
April 19 More Health Delusions, W W Bauer, M D
April 26 Million Murdering Death, W W Bauer, M D

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Thirtieth Annual Meeting held in Chicago Feb 12 and 13, 1934

(Continued from page 1091)

DR MERRITTE W IRELAND, Washington, D C,
in the Chair

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE AMERICAN CONFERENCE ON HOSPITAL SERVICE

Responsibility of the Hospital Trustee and the Relationship Between Trustees and Staff

HON HOWARD S CULLMAN, New York Since, in voluntary hospitals, ultimate responsibility is vested in the board of trustees, the board must be aware of professional matters. That consciousness, however, need only include the appointment of a medical board in whom the trustees have full confidence. The trustees should relegate all professional questions to professional men, confining their activities to the lay aspects of hospital work. The average director feels that he is doing his bit if he helps raise money for actual maintenance charges or expansion programs. If directors, whom I assume to be able business men familiarized themselves with the business policies of hospitals, I am convinced that there would be a minor revolution in many established practices. There are innumerable opportunities in the hospital field for the business man to perform a constructive function, if he will merely trouble to understand that function. A valuable cooperation between various institutions could be achieved in obtaining ambulance appropriations, in large scale purchasing arrangements, in organizing a system for training hospital executives, in discovering and publishing valuable facts on hospital, medical and nursing costs. Many of the difficulties between municipalities and private hospitals would never arise if hospital trustees considered it a part of their function to act as lay ambassadors between the world of science and a somewhat bewildered public. All the authorities vested in the directors of a private hospital are in the case of public institutions, properly within the province of a municipal state or county department of hospitals. I can see no advantage in duplicating or dividing these functions. A board of directors that can serve no useful purpose is a potential menace.

Meddling in professional matters by laymen is pernicious. There is no surer way to undermine the morale of a medical board and disrupt an otherwise excellent service than for lay directors to suggest appointments or promotions to the professional staff. I am strongly opposed to members of the medical staff sitting on the board of trustees. I approve

thoroughly of physicians sending their representatives to board meetings to present the professional point of view, but I do not believe that these representatives should have a voice or vote in the business management of the institution. I am convinced that the doctor-business man is either a second rate doctor or a second rate business man or both. It is unfair and unnecessary to burden a professional staff whose scientific duties should command all its time and attention, with problems that can readily and advantageously be handled by laymen.

The relationship between a hospital board of trustees and the medical staff should closely parallel the relationship between the directors of a corporation and the technical staff—a business-like cooperation based on mutual confidence and mutual understanding.

DISCUSSION

DR NATHANIEL W FAXON, Rochester, N Y The duties of the trustees are legislative rather than executive. They should refrain from directing administrative detail and should never interfere with strictly medical matters. Nevertheless, through proper organization they can not only keep themselves better informed regarding what is going on in their own hospital but they can also be of great assistance to the medical and administrative staff. All hospitals have three groups: (1) the trustees, (2) the administrative staff responsible for the running of affairs and coordinating the efforts of all, (3) the medical staff. Some hospitals have, and there is needed in all, a connecting group—an executive board representing the trustees, the medical staff and the administrators staff. The exact composition of this board is unimportant, there may be a majority of trustees or a majority of medical men; the essential point is a group in which the varied interests of the entire institution may be discussed, an agreement reached and reference made to the body having power to act. Trustees are the connecting link between indirect welfare, represented by hospital and medical care, and direct welfare, represented by the giving of food, clothing and shelter. There has always been a distinction between these two forms of charity. It is impossible to state accurately the amount of charitable work done by voluntary or private hospitals. The American Hospital Association, seeking to obtain at least a cross section of this work, compiled replies from 169 hospitals in nineteen states. These hospitals provided approximately ten million dollars' worth of free service to full charity patients—five million of this was paid for in some way—but the hospitals had to go in debt for the remaining five million. Here is a social financial problem for trustees.

SYMPOSIUM ON THE UNIVERSITY CLINIC

Size and Scope of a University Clinic

DR HENRY S HOUGHTON, Chicago There are now not more than six or eight of all the medical schools in the United States and Canada that are not integrated with the structure, organization, methods and objectives of universities to which they are attached. Inevitably the training of physicians becomes more and more identified with the general field of higher education. The soundest formal education in medicine is the one that "makes the student the unit of education, not the course, the credit hours, nor the faculty." Nothing should induce us, however, to recede from educational standards that are demonstrably good, provided the means of attaining those standards are consistent with common sense, honesty and good will.

How large should a teaching clinic be? I can find no dependable criteria, no single or unitary standard, because of variations in forms of instruction. With amphitheater clinics and large group demonstrations, fewer patients are needed. With students in an apprentice relationship, taking active part in diagnosis and professional care, more patients per student unit are required. Larger clinics, therefore or fewer students, is the answer for this type of teaching. As between these alternatives, a reduction in students appears to be the logical course to advocate. Most of the difficulties now being experienced by practitioners, and most of the hard looks cast by organized medicine at teaching clinics arise not alone from general economic disorders but also from overcrowding and maldistribution.

What field shall a university clinic cover? Definitions are difficult here, because of the varieties of structure and relationship that exist in different institutions. Even within the

category of tax-supported hospitals and clinics, under state or municipal control, there is great variation, from the Nebraska University Hospital in Omaha (no salaried teachers, no hospital charges) to the neighboring University of Iowa (where all members of the teaching staff are on salary, and more than 90 per cent are on the so-called full time basis) in which all classes of patients are admitted. The range in private teaching hospitals and clinics, endowed or substantially self sustaining, also is broad and includes on the one hand institutions like Cornell and the University of Chicago Clinics, which maintain pay clinics as a part of their teaching organization, and on the other, organizations like Rush Medical College which handles its outpatient teaching program through a charitable dispensary endowed for the care of the poor at a nominal charge or entirely free. It is possible to propose basic functions that should be served by these institutions.

(a) Educational and scientific. It is the business of a university in all its divisions to forward the acquisition and diffusion of knowledge. Its success will depend on the wisdom and skill of those who teach in it and it is appropriate to measure its worth by these standards. This applies to clinical service, instruction and research quite as much as it does to economics or theology.

(b) Social functions. These premises have a special application in the care of the sick and the teaching of medicine. The leaders in clinical education are men of recognized professional skill, and their service cannot properly be denied to those who are able to pay for it. If these leaders are giving their undivided time to the university, some form of pay clinic results. If the university claims only a portion of their time those who wish their service pay for it as a matter of private treaty. The result is the same, as a basic economic problem.

(c) Limitations. There are however, natural boundaries in the scope of an instructional clinic conducted in this fashion. It is improper for a university to build up a clinical unit that shall exceed the needs of teaching and research. Whatever is necessary for purposes of study should be provided but expansion beyond that point would represent an unsound educational and social policy.

The topic assigned to this symposium does not refer to it explicitly but there is an implied query as to whether or not universities ought to maintain pay clinics for furnishing teaching material. The American Medical Association officially raises this question and has voiced its disapproval of the conduct of teaching clinics that utilize for instruction those who can and do pay a professional fee for the service rendered. It is appropriate to outline the structure and program of the University of Chicago Clinics.

(a) Student body. Not more than sixty-five undergraduate students in clinical studies can readily be accommodated which is approximately the present enrolment. In addition, there is postdoctorate instruction, and a few students are taking other degrees than the doctorate in medicine.

(b) Formal instruction. This is given in apprentice form. A system of clerkships is employed. Groups are very small. There is intimate participation in the care of patients.

(c) Types of patients. There are three types: full pay, part pay and free. All are available for teaching. In 1932-1933 the total outpatient visits numbered 138,976, new admissions totaled 16,611. The clinic furnishes approximately 15 new patients per instructional day for medical students on service in that division, leaving out of account the advanced students who as interns and assistant residents rotate into the outpatient unit. Full pay patients were from 4 to 6 per cent of the total number. From 85 to 90 per cent of the patients paid something after careful investigation of their ability to pay by the admissions officers. Approximately 10 per cent were wholly free. Determination of capacity to pay is made by trained workers, after a detailed social history has been secured. In judging a patient's ability to pay, the family's resources are compared with the obligations brought by illness. In the inpatient service the picture alters perceptibly, 63 per cent during 1932-1933 paid the full rate, 63.0 per cent paid part of the cost of their hospitalization, 30.7 per cent were wholly free.

Two types of criticism of this theory and practice are voiced. One comes from those preoccupied with problems of medical

economics, who contend that the clinics are being run for profit without reference to teaching needs, that they are making a great deal of money, and that they are damaging the practice of local physicians very much. The other criticism arises from those who look with disfavor on the educational program being followed.

Are the clinics being run for profit? It will suffice to point out that the annual operating deficit in these two services is in excess of \$200,000 annually (1932-1933, \$254,058), covered by endowments and gifts (exclusive of affiliated institutions). No teaching clinic can be expected fully to carry its own costs.

Are the clinical teachers damaging the practice of local physicians? Very little. A survey made late in 1933 showed 32 per cent of the new admissions to be outside of Chicago altogether and 48 per cent outside of the local area of the clinics. The remainder constituted less than 0.8 per cent of the population of the district. Assuming that each of the new outpatients from the South Side paid \$1.29 (which was the average paid by private free and part pay taken together for the period under review) and that each patient made seven return calls at the same rate each of the doctors practicing in the university outpatient department took \$742 during the year out of the local district the total population of which exceeds a million people. If on the other hand these instructors were in the private practice of medicine on the South Side the competitive factor would be at least eight or ten times as great. This is the answer to the accusation so often made that the university is engaged in educating doctors and then taking their prospective clients away from them. In a practical sense the university clinical staff has been taken out of competition. The total of professional fees for all types of service rendered in outpatient and inpatient departments together was \$1060 in 1932-1933 for each full time physician who sees patients in the university, including the affiliated hospitals. Taking account again of charges of local competition and deducting the percentage of patients coming from outside this area the sum would be \$551. If these men were in practice the picture would be very different as far as competitive practice is concerned. I am not including in any of these figures the number of patients actually referred by practicing physicians to the clinics which is in excess of 7 per cent of the total number. In the six years of operation, the volume of patients has risen somewhere near to the optimum for purposes of teaching and study. People do not continue coming to a place that does not serve them properly, especially when they have to pay if they are able to do so as much as they would to run high class physician outside. No one can say that the system I have described is the best. It is in my judgment an important and highly significant experiment in medical education.

The disturbing issues that confront medicine in the United States are not the minor competitive element that exists in university clinics, like this, nor the abuses imputed to free clinics, but the much more difficult and baffling problems of selecting the proper number of the right kind of men to give society intelligent medical care at a fair cost and of finding a way to distribute these men reasonably well throughout our population. Those in charge of teaching clinics are as alive to the perplexities of the situation as any one could be. They have no desire to contribute to the overloading of the profession by teaching great crowds of students, or to its economic distress by developing oversize clinics.

It is conceded that there is a competitive factor in clinics of the type under discussion, but if the competition is honorable it can properly be defended. It is fair and honorable (a) if conducted in accordance with the ethical regulations of the guild, (b) if charges are as carefully adjusted as they are in a high class private practice and are not below those asked by properly equipped private physicians, (c) if it does not expand beyond its obvious requirements for instruction and study.

The Teaching Clinic

DR NATHAN B. VAN ETLEN, New York. The one organization that should control medical education in the United States is the one that represents the whole of the medical profession of the country. All special societies that divert the activities of physicians and weaken the power of the national

organization should confine themselves to the special exhibition of their special interests and give all their political strength to the organization that represents medicine in every corner of the land

Standards of medical education should be those erected by the American Medical Association only, and the ethics of educational institutions should be the same as the personal ethics of every member of the association. Competitive practice of medicine by educational institutions should be eliminated as unfair employment of institutional prestige and advertised excellence in competition with individual physicians, who should have every freedom of opportunity which is their right.

The teaching clinic should be especially careful about competing for patients with their own graduates or with any practicing physicians. More than any other group, teachers are supposed to be exemplars in education and in ethical behavior, and they should subordinate personal ambition to strict adherence to rules of conduct which respect the professional privileges of others. I cannot see the slightest reason for restricting the activity of the university professor, provided there is no implication that he represents the institution in his private work. The really big man in medicine has not gained distinction from large fees but rather from the volume of his work, which has been attracted by the exhibition of unusual skill. The converse is the little soul whose vanity craves the satisfaction of material accumulation.

Competitive practice of medicine by an incorporated medical school or clinic is the corporate practice of medicine, is an operation of unsocial exclusion and combination bargaining, distinctly unprofessional. Such groups should be denied hospital privileges in tax-supported institutions where the rights of the taxpaying physician must be protected. These groups are operating in restraint of individual opportunity and should be vigorously disapproved. The university clinic must never interfere in any way with the return of the patient to the practitioner. A large part of its educational function should be to help the practitioner and never to compete with him.

Some plan must be evolved to control the crowding into an already crowded profession of the two thousand or more American students now enrolled in foreign universities. Some international understandings should be attempted, since the economic distress of physicians seems to be no deterrent to those of our young people who are determined to become physicians.

The university clinic should provide clinical education in clinical centers in our large cities from which clinical knowledge might flow to the surrounding country and to which practicing physicians may come for the continuing education which we all need all our lives. The scope of the university clinic should include postgraduate teaching of any physician in any specialty after he has qualified himself by a definite period of general experience. It would seem to be within the scope of the university clinic to extend graduate education through the medium of county medical societies by lectures supported by local clinical demonstrations planned and executed by university faculties. Graduate teaching carried to the physician has been very irregularly offered but is keenly appreciated by him.

The Outpatient Clinic

DR J H J UPHAM, Columbus, Ohio. This article was published in full in *THE JOURNAL*, March 31, page 980.

DISCUSSION ON THE UNIVERSITY CLINIC

DR JOHN WYCKOFF, New York. I think there can be no question that the medical student must work in a clinic. The first speaker neatly evaded saying how large that should be. Of course, I think none of us know. The school which I have the honor to serve has all the material and more than we need. We feel that to do adequate teaching we need six hospital beds for every clinical clerk, and we feel that we need two outpatient visits daily for every clinical clerk. Dr Van Etten says that the patient should always be returned to the doctor. I don't believe that if the 'always' must be in there it will be possible to teach medicine properly in a university clinic. Do we teach students only disease or do we teach students how patients react to disease? Certainly the patient in the ward which I have in Bellevue Hospital reacts to disease dif-

ferently from the patient one sees in private practice, and, surely, one of the great failures in medical education in the past has been that the student has not had contact of late years with anything except one social stratum. I cannot see how we can produce the type of physician which the profession has a right to demand that we produce unless patients are studied who come from a different social stratum such as is found in a charity hospital. If the patient who comes to the university clinic always is returned to his physician, how, then, is the student to follow the course of ambulatory disease except in the type of patient who is the type of patient that he will probably himself never treat? The other statement which I should like to discuss is the last statement that Dr Upham made. In talking of the pay clinic he seemed to feel that it had no place in undergraduate work. How is the student to be taught as an undergraduate that he must think of the patient's circumstances, if that opportunity is never given to him? It seems to me that it might be a good thing in a medical school to have undergraduate students work in a pay clinic. There was one thing that Dr Houghton said, with which I feel I can agree, and that is that I doubt whether the university teacher and the university clinic are a true source of competition to the practitioner of medicine. I work in a medical school where we do not have full time clinical teachers. I work in a medical school where fifty years ago the clinical teachers were tremendously in competition with their graduates.

DR AUSTIN A HAYDEN, Chicago. I feel that I speak from, and maybe for, the 6,000 physicians of the metropolitan area of Chicago, whose offices and whose services have been through the period of this depression, as they have been through the periods of other catastrophes that have befallen the American people, always at the service of the people without regard for pay. The statement that Dr Upham makes that the free outpatient clinic has become a recognized part of medical education, and a necessary part, goes without saying. That is the accepted way in which the clinical training can be delivered. The size and the scope of the clinic, from which this shall proceed, and the general character of it contain matters that are, as Dean Houghton admits, matters of controversy. According to a survey that was made by the Chicago Medical Society there are 1,000,000 clinic visits in the city of Chicago every year, at least there were in the last year. This number has been appreciably increased within the last year. In 1929 that number amounted perhaps to 600,000. There was no complaint at that time from any institution that that amount of clinical material was not sufficient for the clinical teaching that was to be done. As near as we can estimate, there are about 10,000,000 office visits in the city of Chicago annually, so that we believe that the total matter under discussion represents somewhere around 10 per cent of medical office practice. I do not blame Dr Houghton for not more specifically stating that the size of a clinic will necessarily depend largely on the ideals of teaching and the objects of instruction that the head of the department has who is conducting that clinic. Dr Houghton states that pay clinics have been criticized for being run for profit, without reference to teaching needs. He denies that. But I believe that his denial cannot be absolute. No one has ever said that the University of Chicago was making money out of the clinics that Dr Houghton is conducting. But there has appeared in the conduct of the institution a deficit running in 1932 to \$274,000 which, divided by 65, makes about a \$4,000 deficit on every individual that goes through that school. The futility of this expenditure is emphasized by the fact that 80 per cent of the students who have the opportunity of this educational full time system that Dr Houghton advocates, when it comes to a choice between a full time and a part time system of education in medicine decide against Dr Houghton's system and go to the West Side to old Rush Medical College to finish their medical instruction. It would seem that that is a useless use to put this money to. Dr Houghton has stated that he believes that the use of fees derived from the patients that pay at the clinics of the University of Chicago are a proper source of income for the university by which to cut down their deficit, in other words that by paying doctors at the University of Chicago on a full time basis somewhere from \$742 a year to the munificent sum of \$1,060 a year the fees of those medical men can properly be diverted to the eradication of the deficit

of the university in the operation of its clinics. He thinks that that is a tenable position, in fact, he says that it is fair. In the instance of the University of Chicago no request has ever come to the society for the establishment of a clinic at the University of Chicago. It was not made known to the Chicago Medical Society, and only 6 per cent of the patients that Dr. Houghton has spoken of actually are referred to the clinic by practitioners. So I think the conclusion is justified that as an aid to the general practitioner the university clinic has not been a great help.

DR IRVING S. CUTTER, Chicago When the Ward Memorial Building was constructed, it was the judgment of the faculty that there should be a very strong emphasis placed on outpatient teaching. The question as to whether patients would be received in that clinic who could afford to pay a physician was distinctly answered, positively answered, in the negative. There is a careful social survey of every patient so that under no possibility shall any patient be admitted who can afford to pay a physician. There are thousands of people in all the large cities who are unable to pay physicians and who lend themselves generously, willingly, for clinical teaching. Students are assigned to the several departments in this outpatient clinic so that they work there anywhere from four to six hours daily. I am sure that the clinic that does not take into consideration the human relations of every patient who comes to the clinic falls far short of the principal desirability to the teaching of medicine. It would be very easy for us to have a clinic where patients would be received who might pay more than others. It would be simple and there would no doubt be a gross each year, of possibly \$100,000 or even more if that should be done. It is not done because we feel we have no right to receive any patient and charge that patient, if that patient is able to take care of his own personal medical responsibility. I have the feeling about the so-called free clinic that there is a tremendous increase in mendicancy and that a careless administration of free medical care is bound to result in a whirlwind to the medical profession unless proper safeguards are instituted. It is a good deal like the patient who comes in without a careful social survey and who is later found by the joint emergency relief to have thousands of dollars in the banks. The careful social survey is paramount. After it has been made certain the patient cannot afford to pay, the patient is entitled, somewhere, to genuine, sympathetic, skilful medical care. If it cannot be done in the clinics, the so-called free clinics, it must be done by the city or the county or the state, because that patient needs relief. If the faculty of Northwestern should assume that, because of the gift of a building and of adequate funds with which to equip that building with every modern medical appliance we had the right to charge these individuals as much as the private physician on the outside would charge them, I would feel that we had actually subverted the purpose of the gift. It is unfair that huge funds are solicited from philanthropists to set up great laboratories, clinics and hospitals and then actually enter on the practice of medicine in competition with the private individual. At Northwestern there are between 450 and 550 patient visits daily. That is an adequate number for the students we have to educate. I would not assume for a minute that, if we had 1,000 patients applying daily, we would admit them. We have reached the upper limit of our necessities and beyond that point we would assume that the patients applying for admission would have to be sent elsewhere. I think there are, on the average, about thirty to forty patients each day turned away by the clinic because it is found that they are able to pay a private physician. I am sure that no one of us has any specific point of divergence primarily from any of the authors, but I do feel that, viewing the thing in the broadest principle, from the broadest point of view, from the principle that, after all, the student becomes the doctor ultimately and that the plan under which he is trained influences his life thereafter—viewing the thing thus broadly, we must be very careful indeed that great endowments shall not subvert the student in his tendency thereafter in the practice of medicine. If we are to have general socialization of medicine, perhaps the clinics, some of them that have been mentioned, are wise and good. I doubt very much if that will ever occur. There is one thing quite aside from these papers and that is we have to educate honest men

We have got to educate students who are so fundamentally sound in the practice of medicine that temptation of no sort will swerve them from the direct path.

DR REGINALD FITZ, Boston One of the important things, for teachers in any sort of a clinic to recognize is that, after all, the one really democratic thing in this country is disease. All people get sick. What we have to do is to bring up our students to realize that they must learn how to treat illness in a whole range of different sorts of people. It is unfortunate, if it should occur, that the medical student should be brought up with the idea that the treatment of pneumonia among poor people is any different from the treatment of pneumonia among wealthy people. Dr. Will Mayo said that any good doctor ought to consider himself a trustee of his patient's pocketbook. I wish that some scheme could be brought out by which students could have that taught to them more properly. Often, in teaching clinics, the teachers themselves encourage the students to spend money right and left the idea being that the hospital happens to be so endowed that they can order tests ad infinitum. I should like to see taught more that the physician should spend the patient's money in the wisest possible way. It doesn't make one bit of difference in any given case whether a patient happens to have money or not; the point is that the student has to train himself to think that under no conditions is he going to waste anybody's money, that he has to learn to be economical, sensible and democratic.

DR LANCELY PORTER, San Francisco It has been found that we can get the medical men's cooperation by recognizing that our duty does not end to the state as a medical school when we have graduated a group of well qualified young men to practice medicine. It is our duty to carry medical knowledge to the practitioner. This can easily be done. A few years ago 200 patients a year were referred to the state university medical school. Last year we had more than 3,000, and every month the number is growing. The doctor sends his patient, knowing that he is going to get back a full report on his patient and, furthermore, that he is going to be able to get any further advice he wants about that patient. The doctor is his own social service worker on that case. If a doctor says that a patient can pay nothing or a third or half or all of the costs of x-ray and other expensive diagnostic procedures we accept that as a statement. We don't go behind that. If the medical profession is not competent to do its own social service in such cases honestly, it isn't our business to question the integrity of the men who send us cases. That has been a very valuable thing. The only other point that was brought up that seemed sad was this constant emphasis on the difference between laboratory and clinical medicine. I thought that was dead many years ago. Clinical laboratory work is nothing more than an extension of ordinary methods of examination of the patient.

DR C. R. BARDEEN, Madison, Wis. When one talks in numbers instead of about individuals, there is always involved the question of the profession at large and the public at large, and the only way in which medicine can be satisfactorily practiced is through some sort of agreement as to the general policies in which both are represented. It is not fair to say that it is wholly a question of organized medicine to determine how medicine shall be practiced. The patient has as much to say about it as the physician. But the physician needs to educate the patient as to proper methods. I am strongly in accord with Dr. Lewis that the main thing to aim at is to train good family doctors. The family doctor is to be considered the primary basis of the profession. If that is the case, then we perhaps are overlooking his interest more than other interests in speaking so glibly of how fair it is to establish big public clinics and compete with the family doctor and protect the interests of the specialist. The great run of diseases are not outside the financial resources of the great run of people in normal times. I think that if we are going to train family doctors, one of the first things we ought to think of is not competing too much with the kind of service he can best render.

DR HENRY HOUGHTON, Chicago This has been an extremely helpful discussion. The problem of pay clinics used for teaching purposes has had a number of wallops this afternoon, most of which I think have forwarded our thought

When I said that I thought these clinics ought to be within the limits of the ethics of the guild, I meant exactly within the limitations of ethics of the American Medical Association, of organized medicine, and nothing else. There have to be clinics to teach in, one kind or another, and free clinics are potentially as great sources of abuse as any pay clinic could be. These things have to be watched and regulated. They have to be dealt with honestly, clearly and fairly. There are dangers on both sides. In the clinic that I discussed there has been an effort to keep it at the level that Dr. Wynckoff was talking about. I accept his figure of two patients outpatient cases, daily per student as the ideal. We have not quite attained that ideal. The figure of six beds per clinical clerk we have accepted as being the proper ideal to reach. I have offered an interpretation of certain facts that are open for study. They are questions that arise out of a fundamental teaching educational policy of the University of Chicago, which have been of record for at least twenty years. There was one basic proposition, which I think is worthy of careful study, namely, that the income of physicians comes from the public, whether the physician practices directly and privately or indirectly through an institution. This is an inevitable part of the consideration of the use of pay clinics for educational purposes.

DR. AUSTIN A. HAYDEN, Chicago. I should like to say that I think the establishment of a well set up course in medical economics and perhaps medical history by a practicing physician is something that can be well considered by every medical school in the United States. The last thing I want to say is to the deans. I want to tell them that I think they have taken entirely too little interest in the problems of the practicing physician. When the student has been graduated by their institution, they have largely lost interest in him, or at least their interest has not been manifest by going to his meetings and learning his views. Only by the mutual exchange of ideas can the proper policies be shaped for the guiding of these institutions in the future.

(To be continued)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Personal—At the meeting of the Arkansas State Board of Health, January 18, Drs. Joseph G. Gladden, Western Grove, was named president, Thomas Wilson, Wynne, vice president, and William B. Grayson, Little Rock, secretary.

State Medical Meeting—The fifty-ninth annual meeting of the Arkansas Medical Society will be held at Little Rock, April 16-18, under the presidency of Dr. Leonce J. Kosminsky, Texarkana, and with the Pulaski County Medical Society acting as host. Physicians participating in the program include:

Morris Fishbein, editor of *THE JOURNAL*, Chicago. The Trend of Medical Practice.
Shelby B. Hinkle, Little Rock. Progress in Obstetrics and Gynecology.
Arless A. Blair, Fort Smith. Childhood Tuberculosis.
Isaac G. Jones, De Queen. Conservative versus Radical Surgery.
Roy I. Millard, Dardanelle. Coronary Thrombosis.
John J. Shea, Memphis. Relationship of Allergy to Otolaryngology.
Ira F. Jones, Fort Smith. Uterine Hemorrhage.
Joseph G. Mitchell, El Dorado. Effects of Quinine on the Second and Eighth Nerves.
Oscar W. Bethea, New Orleans. Newer Developments of Physical Diagnosis.
Everett D. Plass, Iowa City. Subject not announced.
George R. Siegel, Clarksville. Endocrine Therapy in the Climacteric.
William Decker Smith, Texarkana. Carcinoma of the Uterus.
Charles S. Holt, Fort Smith. Progress in Surgery.
Henry G. Rudner, Memphis. Symptoms and Treatment of Dysfunction of Colon.
Hallel Unterberg, St. Louis. The Psychoneuroses.
Roland M. Klemme, St. Louis. Trigeminal Neuralgia. Diagnosis and Treatment.
Solomon F. Hoge, Little Rock. Late Syphilis.
William T. Wootton, Hot Springs. National Park Allergy an Every-day Problem.

Dr. Fishbein will address also an evening session on "Fads and Quackery in Healing." The annual banquet and president's ball and reception will be held Tuesday evening.

CALIFORNIA

Health Departments Merge—The San Leandro Health Department and the Alameda County Health Department have combined and will function under the direction of Dr. Ira O. Church, county health officer. Dr. Luther Michael retired as health officer of San Leandro, having held the position many years.

Deaths from Mushroom Poisoning—With eighteen deaths within a week in California from mushroom poisoning, Dr. Jacob C. Geiger, health officer of San Francisco, issued a warning, March 3, advising all except botanical experts to avoid mushrooms unless their species and source are definitely known; it is reported Dr. Geiger urged that consumers purchase their mushrooms from a certified source, pointing out that poisoning is seldom traced to commercial markets.

Professor Not Associated with "Anti-Narcotic League"—Dr. Clinton H. Thienes, professor of pharmacology, University of Southern California School of Medicine, states that he has no connection with an organization called "International White Cross, Anti-Narcotic League, Inc.," with headquarters in San Francisco. In a letter to the executive secretary of the organization he protests against the use of his name as a member of its advisory council on a pamphlet entitled "The Truth About the Narcotic Situation in the United States." Dr. Thienes states that he disapproves the contents of this pamphlet and asks that his name be removed from all literature and other matter prepared, written or sponsored by the organization.

CONNECTICUT

Society News—At the quarterly meeting of the New Haven County Public Health Association in New Haven, March 1, the speakers were Dr. Herbert R. Edwards, acting health officer, on "Examination of Food Handlers," Mr. Sidney G. Davidson, superintendent, Grace Hospital, "Hospital Charges and Other Problems as Related to Public Health," and Mr. Warren J. Scott, director, bureau of sanitary engineering, state department of health, "Various Methods of Sewage Treatment in Connecticut."

Health at Hartford—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended March 24 indicate that the highest mortality rate (22.4) appears for Hartford and for the group of cities as a whole, 12.5. The mortality rate for Hartford for the corresponding week last year was 10.9, and for the group of cities, 11.7. The annual rate for eighty-six cities for the twelve weeks of 1934 was 12.7, as against a rate of 12.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

DISTRICT OF COLUMBIA

Medical Bills in Congress—S. 3186, introduced by Senator McCarran, Nevada, proposes to provide compensation for disability or death resulting from injury to employees in certain employments in the District of Columbia. The term "injury" is defined to include such occupational disease or infection as arises naturally out of employment or as naturally and unavoidably results from accidental injury. An injured employee is to be authorized to secure first aid when necessary "from any qualified physician." If the injured employee desires additional medical attention, he must submit a request therefor to the deputy commissioner, who is authorized by the bill to permit the employee to continue treatment under the physician who rendered first aid treatment, or may direct the employee to submit himself for an examination and/or treatment to a physician or a group of physicians chosen by the deputy commissioner.

GEORGIA

District Meetings—The Fourth District Medical Society was addressed at LaGrange, February 7, among others, by Drs. Robert L. Carter, Thomaston, on "Tuberculosis and Its Surgical Treatment."—The Tenth District Medical Society devoted its meeting, February 14, in Augusta, to a series of clinics.—Dr. Allen H. Bunce, Atlanta, gave a paper before the First District Medical Society, March 21, on "Treatment of Chronic Infectious Arthritis."

Cancer Clinic—The creation of the Atlanta Cancer Clinic for pay patients has been authorized with headquarters in the Medical Building of the Georgia Baptist Hospital, Atlanta.

A diagnostic fee commensurate with the patient's circumstances will be charged, the funds to be used for the maintenance of the clinic. A written report giving the diagnosis and recommendations for treatment will be sent to the patient's physician. Each applicant for admission to the clinic must be accompanied by or bring a letter from his physician. When there is no family physician, a signed statement to that effect will be required. The clinic will have available 370 mg of radium. Dr James L. Campbell has been designated director of the clinic.

ILLINOIS

Illegal Practitioner Found Guilty—Mr S. J. Kuslewski, chief inspector of the Department of Registration and Education of the State of Illinois, reports that E. H. Bernard of Chicago was taken before Judge Helander of the municipal court, February 20, on the charge of practicing medicine without a license. Bernard pleaded guilty, was fined \$100 and was sentenced to one year in the House of Correction.

Health Promotion Week—April 29 to May 5 has been designated as "health promotion week" in Illinois. Tuesday of that week is to be observed as "Child Health Day" in accordance with a proclamation issued by President Roosevelt. Speakers may be secured without local cost either through the state department of public health or from the speakers bureau of the Illinois State Medical Society, 185 North Wabash Avenue, Chicago.

Chicago

Personal—A course on ocular muscles was given at Northwestern University Medical School, April 24 by Dr Alfred Bielschowsky, professor of ophthalmology, University of Breslau, Germany.

Rongetti in Another Penitentiary—Amante Rongetti, who recently completed a term in Fort Leavenworth Kan, is now serving a sentence of from one to fourteen years in the Illinois State Penitentiary at Joliet having been convicted of manslaughter. He was received at Joliet, February 10. In his first trial on the charge of causing a death through an illegal operation, Rongetti was sentenced to death but at the second trial the supreme court committed him to the penitentiary for from one to fourteen years. Rongetti completed a three year sentence at Leavenworth February 6 for violation of the Harrison Narcotic Act (THE JOURNAL, Nov. 7, 1931, p. 1393).

IOWA

Graduate Courses Sponsored by State Society—The speakers bureau of the Iowa State Medical Society inaugurated three courses on graduate medical education recently. One on general therapeutics opened at Creston February 21 continuing weekly until April 25. Out-of-state speakers participating in this course are Carl R. Moore, Ph.D., Drs. Paul Cannon, Clifford J. Barborka, Samuel M. Femberg, George W. Hall, and Oliver S. Ormsby, all of Chicago. George B. Eusterman, Rochester, Minn., and Arthur L. Tutum, Madison, Wis. The course on neurology and psychiatry was initiated March 1, at Oskaloosa, these weekly sessions ending May 3. Dr. Alfred W. Adson, Rochester, Minn., was the visiting speaker. Infectious diseases is the theme of the third course which opened in Mount Pleasant, March 2. The concluding lecture in this weekly series will be May 4. One out-of-state speaker participated in this group, Dr. Fred W. Garde, Rochester.

KANSAS

Personal—Dr. Fay E. Garther, Lenora, has been appointed health officer of Norton County. Dr. Eber Reeves has been named health officer of Decatur County. Dr. Charles McKinley has been appointed physician at the state penitentiary, Lansing, succeeding Dr. Robert H. Moore, resigned. Dr. Darrel L. Evans has been named health officer of Riley County, succeeding Dr. John R. Mathews, Manhattan, who has resigned to engage in private practice in Glenwood Springs, Colo. He had held the position since 1923.

KENTUCKY

Private Physicians to Immunize Children—The Louisville city health department under Dr. Hugh R. Leavell, has announced a new policy with respect to immunization of school children, under which all children whose parents are able to pay are to be sent to private physicians. Formerly all school children were immunized by the health department at public expense. In cooperation with the Jefferson County Medical Society the department is arranging a policy of having patients pay for medical service according to their ability and the

society is preparing a list of physicians willing to accept these "part pay" patients. Steps have recently been taken to readjust also the hospitalization of the county indigent, the entire budget relating to health and hospitalization having been transferred from the county welfare department to the health department. Dr. Ben Wilson Smock has recently been appointed assistant to Dr. John D. Trawick, county health officer, and comprehensive plans are under way for coordination of the city and county health departments.

Society News—A symposium on the common infections was presented at a meeting of the Jefferson County Medical Society March 5, by Drs. Charles Dwight Townes, Will R. Pryor, Ayrine E. Bell and Karl N. Victor. Dr. William T. Pride, Memphis, Tenn., addressed the society, March 19, on "Gnathostome Repairs of Old Lacerations at the Time of Delivery" under the auspices of the Louisville Obstetrical and Gynecological Society. Drs. Louis Feid, Jr. and Clifford J. Strachley, Cincinnati, addressed the Mason County Medical Society, Mayville, February 14, on treatment of benign uterine hemorrhage and classification of heart diseases, respectively.

LOUISIANA

State Medical Meeting at Shreveport, April 10-12—The fifty-fifth annual meeting of the Louisiana State Medical Society will be held at Shreveport April 10-12 with headquarters at the Washington Youree Hotel, and under the presidency of Dr. Carl A. Weiss, Baton Rouge. Included in the scientific program are the following physicians:

Joseph F. Kniphton, Sr., Shreveport, The Failing Heart of Middle Life.
John H. Musser, New Orleans, Treatment of Cardiovascular Syphilis.
Emmerich von Haam, New Orleans, Importance of Biopsy in the Diagnosis of Cancer.
Harold J. Kearney, New Orleans, Bronchoscopic Aspiration in the Treatment of Lung Suppuration.
Arthur A. Herold, Shreveport, Pathology: The Basis of Scientific Medicine.
Vernon D. Hargrove, Shreveport, A Review of 112 Cases of Amebiasis.
Martha Eleanor Cook, Lake Charles, A Simplified Treatment of Infantile Diarrhea.
Charles W. Duval, New Orleans, The Host Cell Reaction to Invasion by Bacillus of Leprosy.
Francis J. LeJeune, New Orleans, Hoariness: Its Significance.
Denn Lewis, Baltimore, President, American Medical Association, Chicago, The Surgical Lesions of the Breast.
Leon J. Menville, New Orleans, Bone Tumors from a Radiologic Standpoint.
Peter C. Raffagnino, New Orleans, The Chronically Diseased Cervix as a Focus of Systemic Infection.
Alec J. Lelerc, Monroe, Suppurative Otitis Media.
Rufus Jackson, Baton Rouge, Nonpurulent Accessory Sinusitis.
George A. Meyer, New Orleans, Hypotension in Relation to Toxemia in Pregnancy.
Leon Gray, Shreveport, Squint and Its Treatment.
Rudolph Matis, New Orleans, On Vascular Surgery in Louisiana: A Historical Review.
Wiley R. Buffington, New Orleans, Importance of Recent Advances in the Etiology and Treatment of Certain Conjunctival and Corneal Diseases in General Medicine.
Clifford P. Rutledge, Shreveport, Diagnosis and Treatment of Intoxication by Use of the Barium Enema Under Fluoroscopic Control.
Edward J. King, New Orleans, Induction of Labor by Medical Means Contrasted with Surgical Methods.
George C. Britalora, New Orleans, Compression Fractures of the Spine.

MAINE

Society News—Dr. Sidney C. Dyrville, Newton, Mass., addressed the Cumberland County Medical Society, February 23, on "Correlation of Clinical and Pathological Findings in Bright's Disease." The Portland Medical Club heard Dr. Henry P. Johnson discuss "Some Effects of Climatic Changes on the Mucous Membranes of the Upper Respiratory Tract," February 6. Speakers before the Kennebec County Medical Society in Gardiner, February 15, included Drs. Bernhardt I. Wulff, Waterville, on "Intravenous Urography," and Frank B. Bull, Gardiner, "Blood Transfusions." At a meeting of the Oxford County Medical Society in Rumford, February 23, Dr. Warren E. Kershner, Bath, spoke on physicians' liability insurance and mastoid problems in general practice.

MASSACHUSETTS

Dr. Irving Appointed Professor of Obstetrics—Dr. Frederick Carpenter Irving has been appointed William Lambert Richardson professor of obstetrics at Harvard Medical School. He is the first incumbent of the chair, which was recently created under the will of Dr. Richardson, former professor of obstetrics and dean of the medical school. Dr. Richardson bequeathed \$100,000 to endow the professorship and the Harvard Corporation voted to name it in his honor. Dr. Irving was born in Gouverneur, N. Y., in 1883. Graduating from Harvard Medical School in 1910, he engaged in practice in Boston the same year, and became affiliated with the school in a teaching capacity in 1922.

Society News—Dr Thomas J O'Brien, Boston, addressed the South End Medical Club, March 20, on medical legislation. —At a meeting of the Middlesex East District Medical Society in Stoneham, March 14, Dr William R Morrison spoke on "Stomach Surgery."—The clinical and experimental observations on the effect of total thyroidectomy was the discussion before the Harvard Medical Society March 13, speakers were Drs Samuel A Levine, Eugene C Eppinger, Philip Shambrough, Morton G Brown, Max T C Schnitzer and Elliott C Cutler, and Margaret E Sawyer, Ph D.—Among the speakers before the New England Roentgen Ray Society, March 16, was Dr Edward C Vogt on "The Esophagus and Gastro Intestinal Tract in Infants and Children."—Drs Harry C Solomon, Houston H Merritt, Jr, and Merrill Moore conducted a symposium on neurosyphilis before the Boston Society of Psychiatry and Neurology, March 15 and Dr Robert E Fleming and Elmer Stotz, BS, discussed "The Blood and Spinal Fluid Alcohol in Abstainers, Chronic Alcoholics and in the Psychoses."

MICHIGAN

Dinner to Dr Kamperman—Dr George Kamperman, Detroit was honored by a dinner, given by his former residents, February 20, to mark his fifteenth anniversary as head of the department of obstetrics and gynecology of Harper Hospital. Following the dinner, Dr Owen C Foster unveiled a large framed "photomontage," a composite photograph depicting characteristic Harper Hospital scenes which serve as a background for photographs of Dr Kamperman and surgeons trained by him since his appointment. It now hangs in the obstetric club room of the hospital. Dr Harold C Mack presented a bound testimonial and guest book containing letters and photographs of former and present residents.

County Secretaries' Conference—At the annual conference of the county secretaries of the Michigan State Medical Society in Ann Arbor, March 7, the following program was presented:

Reuben L Kahn ScD, Ann Arbor, Recent Developments in Immunology
Dr Carl E Badgley, Detroit Traumatic Surgery
Dr Cyrus C Sturgis Ann Arbor Therapy in Anemias
Dr Charles L Brown, Ann Arbor Therapy Limitations in Hypertension
Dr Ledru O Geib and Henry F Vaughan, Dr PH, Detroit, Our Preventive Medicine Program
Dr James B Bradley Eaton Rapids Legislation
Dr Louis LeFevre Muskegon, County Society Program in the Care of Indigents
Dr James D Bruce Ann Arbor Progress and Planning in Postgraduate Education
Drs LeFevre John B Jackson Kalamazoo Herbert E Randall and Carl F Moll Flint J Milton Robb Detroit Richard R Smith and Burton R Corbus Grand Rapids Medical Problems and Policies

In addition, Dr Carl D Camp, Ann Arbor, conducted a neurologic clinic.

MINNESOTA

Personal—A farewell dinner was given in honor of Dr Elmer C Bartels, January 23, by fifty-five physicians of Duluth. Dr Russell J Moe was toastmaster. Dr Bartels has since gone to Springfield, Ohio, to practice.—The University of Minnesota recently received a gift of \$500,000 for the advancement of medical research from Drs William J and Charles H Mayo, Rochester.

Dr Allen Honored on Hundredth Birthday—Dr Wilson A Allen, Rochester, was presented with a resolution of the Olmstead-Houston-Fillmore County Medical Society congratulating him on his one hundredth birthday and creating for him as a special honor, the title of emeritus member with the privilege of active membership, without payment of dues. A telegram offering congratulations was also received by Dr Allen from President and Mrs Roosevelt. Dr Allen observed his birthday, March 6 but because he was confined in a hospital, no special celebration was held. The resolution points out that Dr Allen has been a member of the Minnesota State Medical Association since its organization. A resolution was also adopted by the common council of the city of Rochester in recognition of Dr Allen's centenary. Dr Allen served as mayor of Rochester for one term 1895-1896. He graduated from Hahnemann Medical College and Hospital, Chicago, in 1879.

MISSISSIPPI

Bill Introduced—S 506, to amend the law relating to privileged communications proposes that a physician shall not be required to disclose such a communication in any legal proceeding unless the patient expressly waives the privilege at the time of the trial. The present law prohibits such a dis-

closure in any "civil" proceeding "except at the instance of the patient."

Society News—Speakers before the Central Medical Society, February 6, included Drs Robert B McLean, Jackson, on "Urticaria and Angioneurotic Edema," and Robin Harris, "Association of Scintillating Scotoma and Nasal Accessory Sinus Disease."—The meeting of the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg, February 13, was devoted to a discussion of the common cold.

NEBRASKA

Society News—A symposium on obstetrics was presented before the Cedar, Dakota, Dixon, Thurston and Wayne Counties Medical Society, Emerson, February 20 by Drs Leo J Killian, Wakefield, John Buis, Pender, Paul F Suman, Wayne, Ralph C Gramlich, Walthill, Stuart H Cook and Glen E Peters, Randolph. —At a meeting of the Sixth Council District Medical Society, Osceola, January 16, Omaha physicians presented addresses. Drs Rodney W Bliss, on peptic ulcer, Abram E Bennett, traumatic encephalitis, and Charles A Owens, Jr, transurethral resection.—Dr Abraham Levinson, Chicago, addressed the Omaha-Douglas County Medical Society Omaha, March 27, on diagnosis and treatment of meningitis. Three physicians of Council Bluffs, Iowa, addressed the society March 13, as follows. Drs Gordon N Best, on "Chronic Obstruction of the Duodenum", Maurice C Hennessy, "Foreign Bodies Producing Bowel Obstruction" and Karl R Werndorff, "Reconstruction of Function in Paralyzed Extremities."—Drs Maurice E Grier and Lloyd O Hoffman, Omaha, addressed the Otoe County Medical Society, Nebraska City, April 9, on infections of the genital tract.

NEW JERSEY

Bill Passed—A 245 has passed the assembly, proposing to amend the dental practice act by authorizing the revocation of a license to practice dentistry, if the licensee violates any of the rules or regulations which the state board of registration and examination in dentistry may hereafter adopt with respect to the practice of dentistry.

NEW YORK

Bill Passed—A 417 has passed the assembly, proposing to amend the pharmacy practice act by providing (1) that a drug shall be deemed to be misbranded within the meaning of the act if its package does not bear a statement of the percentage of barbituric acid contained therein, but (2) that the act shall not apply to the manufacture and sale of proprietary medicines except those containing poisons, deleterious and/or habit-forming drugs and chemicals.

Bills Introduced—A 1926, to amend those provisions of the medical practice act relating to osteopathy, proposes (1) to designate osteopaths as "osteopathic physicians", (2) to forbid licensed osteopaths to perform surgery with the use of instruments, except to cut the umbilical cord, to circumcise, to use forceps for delivery, to repair the perineum, to lance superficial abscesses and to repair skin lesions, and (3) to permit licensed osteopaths to use and prescribe narcotics, anesthetics, antiseptics, vaccines, antitoxins and serums. A 1927, to amend the provisions of the medical practice act relating to osteopathy, proposes that a license to practice osteopathy (1) shall not permit the holder to perform surgery with the use of instruments, except to cut the umbilical cord, to circumcise, to use forceps for delivery, to repair the perineum, to lance superficial abscesses, and to repair skin lesions, and (2) shall permit the holder to use and prescribe metaphen, resorcinol, zinc oxide, hydrogen peroxide, mercurochrome, iodine, potassium permanganate, menthol, thymol, ichthyol, sulphur, alcohol spiritus frumenti, colloidal silver compounds, silver salts, adrenalin, ephedrine, epinephrine, iodoform, bichloride of mercury, phenol, opium and its derivatives, cocaine and its salts, novocain, procaine, veronal, luminal, amytal and its sodium salts, chloroform ether, nitrous oxide, ethyl chloride, avertin, butyn, toxic toxin antitoxin antitoxin staphylococcus vaccine, streptococcus vaccine, polyvalent vaccine, autogenous vaccine, pneumococcus vaccine, tetanus antitoxin, typhoid vaccine, neoipax and tetraiodophenolphthalein for use in x-ray diagnosis.

New York City

New Members of Board of Health—Dr Haven Emerson, professor of public health administration, Columbia University College of Physicians and Surgeons and Dr Frank L Babbott, Jr, president of Long Island Medical College Brook-

lyn, were appointed members of the board of health by Mayor La Guardia in February. Dr. Emerson was health commissioner of New York from 1915 to 1918. The new members succeed Drs. Harry P. Swift and Rand Percy Crandall.

Salmon Lectures—Dr. Charles Macfie Campbell, professor of psychiatry, Harvard University Medical School, Boston, will deliver the 1934 series of Salmon Lectures at the Academy of Medicine, April 13, 20 and 27 (*THE JOURNAL*, January 27, p. 300). The title of the first lecture will be "Trends in Psychiatry," the second, "Classification Versus Dynamic Analysis," and the third will embody conclusions and suggestions.

Committee to Promote Sanitary Dispensing of Foods—There has been organized in New York a Committee for the Study and Promotion of the Sanitary Dispensing of Food and Drinks, the purpose of which is to educate the public to demand sanitary practices in the dispensing of food and drinks in public eating places. Dr. Alec N. Thomson is chairman and Homer N. Calver, former editor of the *American Journal of Public Health*, is executive officer. The committee urges the public to protest to the management against all unsanitary practices observed, to commend the management of places that uphold high sanitary standards and to report by name and address to the board of health all public eating places violating high standards.

Society News—Speakers at a meeting of the Medical Society of the County of New York, February 26, were Drs. Thomas Francis, Jr., on "Diagnosis and Treatment of Influenza," Henry T. Chickering, "Prognosis and Treatment of Lobar Pneumonia," and George G. Ornstein, "Pulmonary Atelectasis."—Dr. Boris M. Fried, among others, addressed the New York Pathological Society, February 22, on "Allergic Inflammation of the Lungs."—A symposium on "Indications for Roentgenotherapy in Malignant Disease of the Ear, Nose and Throat" constituted the program of the New York Roentgen Society, February 19, speakers were Drs. Maurice Lenz, Arthur P. Stout, Alfred A. Schwartz, John D. Kerran, Jr., Robert E. Buckley and George H. Semken.—A symposium on acute and chronic emphysema was presented before the New York Surgical Society, March 14, by Drs. John F. Connors, Harold Neuhof, Adrian V. S. Lambert and Walton Martin.

—The staff of Memorial Hospital presented a symposium on gastro-intestinal tumors before the Society for the Advancement of Gastro-Enterology, February 28, among the speakers were Drs. James Ewing, Lloyd F. Craver and George T. Pack and Edith Quimby, associate physicist.—Drs. William B. Castle, Boston, and Robert L. Moorhead addressed the Medical Society of the County of Kings, February 20, on "Modern Concepts of Anemia and Its Treatment" and "Cancer of the Larynx—Importance of Early Diagnosis," respectively.—At a meeting of the International and Spanish Speaking Association of Physicians, Dentists and Pharmacists, January 19, speakers were Drs. Franz Groedel, Frankfurt, Germany, on hydrotherapy, Burton T. Simpson, Buffalo, on radium therapy, and George Henry, on psychotherapy. Dr. Jacob M. Gerslberg, who was reelected president, gave his official address on the life of Professor Ramon y Cajal of the University of Madrid. At the February meeting a symposium on gastro-enterology was presented, with the following speakers: Drs. L. Lee MacPhee, Boston, Leopold Lichtwitz, and George E. Binkley, and John Oppie McCall, D.D.S.

PENNSYLVANIA

Ten Deaths from Psittacosis in Pittsburgh—At least ten deaths and several cases of psittacosis recently occurred in Pittsburgh as a result of contact with sick parrots in the pet department of a large department store. Psittacosis was first suspected when it became known that seven deaths had occurred among employees on only two floors of the store within two weeks, supposedly of pneumonia. A physician called to care for the eighth employee believed to have pneumonia had learned that the two floors of the store were decorated with parrots and parakeets. He notified the city health department. Examination revealed that they had the disease and postmortem examination of the eighth patient from the store confirmed the diagnosis. The store in question immediately destroyed all its birds, discontinued the pet department and fumigated the store. All psittacine birds in the city were quarantined. The epidemic was traced to a shipment of 130 birds from California in January, of which three were dead on arrival, it was said. Dr. Lucius F. Badger of the U. S. Public Health Service went to Pittsburgh to conduct an investigation, March 17, after which he announced that the epidemic appeared to be under control. Later reports stated that two other pet shops had received shipments in which birds were sick or dead and

that one case of psittacosis had been diagnosed from each shop. The San Francisco *Examiner* reported, March 17, that the California State Board of Health was investigating the report that some of the birds sent from California were shipped in violation of specific orders from the board.

Philadelphia

Gerhard Medal Awarded—The Pathological Society of Philadelphia will award the William Wood Gerhard Gold Medal to Dr. George H. Whipple, dean of the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., at a meeting April 12. Dr. Whipple will deliver the annual Conversational Lecture of the society, his subject being "Regeneration of Hemoglobin and of Blood Plasma Proteins Controlled by Diet Factors."

Impostor Claims Relationship—A man has recently circulated among physicians in Washington, D. C., claiming to be a brother of Dr. Joseph McFarland, Philadelphia, and asking financial aid, it is reported. His story was that he had run past a stop light and damaged the car of another person, for which he was arrested and fined \$25 which took all his ready cash. He stated that unfortunately he was without identification but knowing that pathologists would know his "brother," he took the liberty of asking aid. He is a slender man with steel gray hair, slightly bald about 60 years old, well dressed, and with several teeth missing in front. Dr. McFarland has no brother.

Society News—Speakers who addressed the Philadelphia Academy of Surgery, March 5, were Drs. Robert H. Ivy and Lawrence Curtis on "Experience with Newer Procedures in Surgery of the Cleft Palate," and Alexander Randall, "Advances of Prooperative X-Rays in Kidney Tumor in Children."—Dr. Lyndon G. Richards, Boston, addressed the Philadelphia Laryngological Society, March 6, on "Sinusitis in Children: Diagnosis and Treatment."—Drs. William C. von Glahn and Alwin M. Pappenheimer, New York, were guest speakers at the meeting of the Pathological Society of Philadelphia, March 8, on "Relation Between Rheumatic and Subacute Bacterial Endocarditis."—Dr. Gabriel Tucker, among others, addressed the Philadelphia Pediatric Society, March 13, on "Obstructive Disperser in Children."

WASHINGTON

Society News—Dr. Andrew C. Ivy, Chicago, will be the guest speaker at the annual open meeting of the Tacoma Surgical Club, April 7. Dr. Ivy will lead a symposium on modern knowledge of the physiology of the gastro-intestinal tract and will speak in the evening on "Applied Physiology of the Alimentary Tract." Demonstrations will be held at Tacoma General Hospital.—Dr. Howard L. Updegraff, Los Angeles, addressed the King County Medical Society, Seattle, March 19, on "Methods of Reconstructive Surgery."

WISCONSIN

William Snow Miller Lecture—Chuncey D. Leake, Ph.D., professor of pharmacology, University of California Medical School, San Francisco, delivered the eighth annual address under the William Snow Miller Lectureship at the University of Wisconsin, March 23. Dr. Leake's subject was "Relations of Medicine and Art."

Personal—Dr. Gilbert E. Scamman, Milwaukee, has been appointed acting head of the Northern Hospital for the Insane, Winnebago, replacing Dr. Peter P. Bell, resigned.—Dr. William M. Sweener, Milwaukee, celebrated his fiftieth anniversary in the practice of medicine, March 11. Dr. Sweener was a founder of the old Milwaukee Medical College now a part of Marquette University, and served as professor of diseases of children from 1894 to 1904.—Dr. Albert Schmidt, Liberty Grove, celebrated his ninetieth birthday in January, he was greeted by all the residents of the village.—Dr. James E. Newton was recently appointed mayor of Hudson.

Fifty Years in Practice—Residents of Oostburg and the contiguous territory gave a reception and banquet February 20, in honor of Dr. Edward Was, who has practiced fifty years in the community. Dr. Was, a native of The Netherlands, graduated from Rush Medical College, Chicago, in 1884 and began practice in Oostburg immediately. Speakers at the banquet included Drs. William H. Gunther, William Van Zanten, Otho A. Fiedler, Otto T. Gunther, Harry H. Heiden and J. P. Zolten, all of Sheboygan, Emmett F. Guy, Oostburg, John E. Guy, Milwaukee, Anthony Voskuil, Cedar Grove, and Robert M. Nichols, Sheboygan Falls. A plaque was presented to Dr. Was, inscribed with the legend "Fifty Years of Faithful Service, 1884-1934, from the Village of Oostburg."

GENERAL

Journal for Digestive Diseases—March 15 marked the first publication date of the *American Journal of Digestive Diseases and Nutrition*. The journal will be issued monthly from Fort Wayne, Ind. Dr. Frank Smithies, Chicago, is editor, and Dr. Beaumont S. Cornell, Fort Wayne, supervising editor.

Death Rate Among Policyholders—The death rate for 1933 among the industrial policyholders of the Metropolitan Life Insurance Company in the United States and Canada was 802 per thousand, the lowest ever recorded for this group, this in spite of a sharp increase in January in deaths from influenza, and the principal degenerative diseases. Decreases took place in deaths from tuberculosis, pneumonia, conditions arising from pregnancy and childbirth, diphtheria, whooping cough and measles. The death rates for diarrhea and enteritis and for fatal machinery accidents showed no change from their previous low points reached in 1932. Cancer, heart disease and diabetes recorded higher mortalities than ever before, even when the fact is taken into account that a larger proportion of the insured group is now in the older age groups. Accidental deaths, especially automobile fatalities, increased, though the number of deaths of children as a result of automobile accidents has diminished. The 1933 mortality rate for falls was the highest in fifteen years.

Epidemics of Measles—It has been estimated that 7,000 cases of measles have occurred in Washington, D. C., since January 1, eleven persons have died. This is said to be the heaviest epidemic since 1921 in the capital. Philadelphia newspapers reported, March 18, that 10,688 cases had been reported to the city health department since January 1, with forty deaths. Baltimore had 1,988 cases reported between January 1 and March 14. It was reported more than 2,500 cases had occurred in El Paso County, Texas, from January 1 to March 6, with fifty-six deaths. Fifteen members of the freshman class at Harvard University, Cambridge, Mass., were stricken, the *New York Times* reported, March 22. Other epidemics have been reported from the following towns: Toledo Ohio, 700 cases during the first nine days of March, Springfield, Ill., 800 cases between February 1 and March 18, Chattanooga, Tenn., 310 cases in the first two weeks of March, Salt Lake City, Utah, 506 cases during the week preceding March 4. The U. S. Public Health Service reported that 30,806 cases had been reported from forty-six states during the week preceding March 4, compared with 14,081 for the corresponding week of 1933.

Society News—Dr. James R. Garber, Birmingham, Ala., was elected president of the Southern Interurban Gynecological and Obstetrical Society at a meeting in Birmingham, February 17. Dr. Willard R. Cooke, Galveston, Texas, vice president, and Dr. James L. Seibold, Birmingham, secretary. Drs. Everett D. Plass, Iowa City, and George P. Muller, Philadelphia, were guest speakers. The Society for the Study of Asthma and Allied Conditions will hold its spring meeting in Atlantic City, April 28. The tenth annual scientific meeting of the American Heart Association will be held in Cleveland, June 12 at the Cleveland Hotel. The program will be devoted to arteriosclerotic heart disease. This association moved its headquarters, March 30, to the RCA Building, 50 West Fiftieth Street, New York. The congress of the Association of French-Speaking Physicians of North America is to be held in Quebec, August 27-29, in conjunction with the twenty-third session of the Association of Physicians of the French Language, which includes members from France and Belgium. The American Association on Mental Deficiency will hold its annual meeting at the Hotel Waldorf-Astoria, New York, May 26-29. The afternoon session, May 29, will be held jointly with the American Psychiatric Association. Dr. Groves B. Smith Godfrey, Ill., is secretary of the association. Dr. Philip H. Kreuscher, Chicago, was elected president of the Northwest Regional Conference in St. Paul, Minn., February 25, succeeding Dr. Benjamin F. Bailey, Lincoln, Neb.

Medical Bills in Congress—*Changes in Status*. The Independent Offices' Appropriation Bill, H. R. 6663, which has been passed by the House and the Senate over the veto of President Roosevelt (Public Law No. 141), provides, among other things, that any veteran not dishonorably discharged suffering from disability, disease, or defect, who is in need of hospitalization or domiciliary care and is unable to defray the necessary expenses therefor, shall be furnished such hospitalization or domiciliary care in any Veterans' Administration facility, within the limitations existing in such facilities irre-

spective of whether the disability, disease, or defect was due to service. A statement under oath by the veteran on such form as may be prescribed by the Administrator of Veterans' Affairs must be accepted as conclusive proof of inability to defray necessary expenses. S. 2688 has been reported to the House, with recommendation that it pass. It validates payments made by disbursing officers of the army for the medical and hospital treatment of members of the Reserve Officers' Training Corps and of members of the Citizens' Military Training Camps who contracted disease in line of duty while en route to or from and while at camps of instruction. *Bills Introduced*. S. J. Res. 92, introduced by Senator O'Mahoney, Wyoming, proposes to create a commission to formulate a permanent national policy with respect to benefits for veterans and dependents of veterans. S. 3111, introduced by Senator McKellar, Tennessee, proposes to authorize the erection of a veterans' hospital in middle Tennessee. S. 3175, introduced by Senator Couzens, Michigan, proposes to authorize claims to withdraw alcohol tax free. H. R. 8818, introduced by Representative Welch, California, proposes to extend the benefits of the United States Public Health Service to fishermen, trappers, net tenders, and other persons subject to the laws relating to American seamen. H. R. 8846, introduced by Representative Dockweiler, California, proposes to provide an increase of compensation for certain veterans' widows.

Government Services

Veterans' Compensation Restored

Pensions or compensation to veterans whose benefits were reestablished by the passage, over the President's veto, of the Independent Offices' Appropriation Act for the fiscal year 1935, will be restored with the least possible delay, the Administrator of Veterans' Affairs has announced. The Veterans' Administration estimates that approximately 330,000 World War veterans, 180,600 Spanish-American War veterans and 34,900 dependents of Spanish-American War veterans will be affected by the new legislation, at an increase in cost to taxpayers of approximately \$83,000,000 annually. Any veteran not dishonorably discharged who suffers from disability, disease, or defect, and who is in need of hospitalization or domiciliary care, and who is unable to defray the necessary expenses therefor, is to be furnished such hospitalization or domiciliary care in any Veterans' Administration facility, within the limitations of such facilities, irrespective of whether the disease, disability, or defect was due to service. A statement under oath by the veteran must be accepted as conclusive evidence of inability to pay. Under section 200 of the World War Veterans' Act certain disabilities were declared presumptively to be of service origin. The Economy Act of March 20, 1933, severed the service connections based on presumptions. The new act reestablishes these presumptions. The new law also restores to veterans with service-connected disabilities the same rate of compensation that was payable to them prior to March 20, 1933, except that the rate paid to veterans whose disabilities are service connected by presumptions is to be 75 per cent of the rate paid prior to the date named. Veterans of the Spanish-American War, who entered service on or before August 12, 1898, and persons who served in the Boxer Rebellion or Philippine Insurrection, who were receiving pensions for disability or age, March 19, 1933, are entitled by the new law to receive not less than 75 per cent of the pension then being paid, subject to certain restrictions relating to the financial need of the veteran, and whether or not the veteran is hospitalized. All laws in effect March 19, 1933, granting monetary benefits to veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection, are reenacted in their entirety, subject to the limitations prescribed in the new law and to such reduction in pensions, not exceeding 25 per cent, as may hereafter be made. The provisions of section 213, World War Veterans Act, are reestablished, whereby a person who is injured as a result of training, hospitalization or medical or surgical treatment or examination is awarded compensation on the same basis as if the condition were incurred in the military or naval service. Hereafter, service-connected money benefits payable to veterans of the World War are to be entitled compensation, not pension. Former compensation rates paid to totally blind World War veterans are reestablished, except where the veteran is furnished hospital care by the government and except as to cases involving fraud, mistake or misrepresentation.

March 10 1934

The Battle of the Barbiturates

The controversy that has arisen over the dangers of the use as hypnotics of the large group of derivatives of barbituric acid was mentioned in *THE JOURNAL*, February 10. It has been continued in the medical press to such an extent that it has been termed by the *Lancet* the Battle of the Barbiturates. Sir William Willcox, who struck the note of warning is still the protagonist on the side of danger. His experience as a toxicologist is unrivaled but the leading psychiatrists oppose him. In the *Lancet* he repeats his warning that the barbiturates have a powerful action on the nervous system and that care is required in their repeated daily use. It is constantly brought to his knowledge that in therapeutic doses symptoms such as mental depression, drowsiness, visual hallucinations, vertigo, ataxic gait, indistinct speech, squint, nystagmus and paralysis of the limbs are common results. Indeed a complex of symptoms identical with those of cerebellar disease, postrolateral sclerosis, epidemic encephalitis, bulbar paralysis or meningitis may be produced. Professor Richards of Aberdeen has recently sent him notes of three cases in which loss of memory and automatism followed daily therapeutic doses of barbiturates, and as a result an excessive number of tablets was unconsciously taken. Sir William disputes the figure that out of 5147 suicides in 1931 only 13 were due to barbiturates (*THE JOURNAL*, February 10, p. 468). In 1933 Sir William treated eighteen cases of dangerous poisoning. Most of the deaths occur in persons who have been taking the drugs in repeated daily doses. He fully admits their value in the treatment of mental disorder.

Sir James Purves-Stewart, a neurologist, has observed three cases of paralytic syndromes of the mesencephalic, cerebellar and spinal type respectively following chronic use of barbiturates in therapeutic doses for hypnotic purposes. Other correspondents give further evidence of the increase of cases of poisoning due to barbiturates. From 1909 to 1914 there were admitted into the hospitals in Budapest thirty-five cases of barbituric poisoning, but in 1932 there were admitted into one hospital of that city eighty-seven cases of barbituric poisoning and in addition phenobarbital had appeared on the list and was responsible for eighty cases. The argument on the other side is that the barbiturates have been used with safety and good results in an enormous number of cases. Sir Maurice Craig, a psychiatrist, wishes that Willcox had a few years' experience in the treatment of mental disturbances, for he would then appreciate what prescribing for these patients entails. He also considers it satisfactory that the suicide rate and accidental death rate taken together for barbiturates do not exceed two thirds of 1 per cent of the suicide rate in the country.

Professor Richards uses the term 'automatism' for the mental condition induced by the habitual taking of barbiturates which is so dangerous and yet has never been stressed in publications on the subject. Knowledge for the need of another tablet seems to persist, while the memory is so affected by the drug that the patient does not realize that he has already satisfied the need and automatically repeats the dose at intervals.

The Tax on Insulin

A protest has been evoked by the imposition of a 33 per cent tax on imported insulin. In the house of commons Commander Locker-Lampson described it as a mistake in morals as well as in medicine and a tax on poverty and disease. There were in this country 100,000 victims of diabetes whom

this tax exploited. For the government, Mr. Shakespeare replied that our experience since the imposition duties had shown that they did not necessarily mean an increase of price. When insulin was first manufactured in this country in 1923 the price was \$6 for 100 units. In 1933 two firms in this country were producing it at 48 cents and a third at 40 cents retail. After the imposition of a duty, the British price had been reduced: two firms were producing it at 44 cents and a third at 34. The price of the imported product had not risen in spite of the duty but remained at 34 cents. Insulin was cheaper in this country probably than in any other country in the world except possibly Scandinavia. Recently representations were made by American and Canadian producers to British producers that if the price was reduced any more it would be impossible to compete and produce it at an economic level. The fall of British prices since the imposition of the duty can be explained as either due to further improvements in the method of manufacture or to the fact that the profit was so large as to allow the reduction. The fact that Danish insulin after paying the 33 per cent duty is sold at the same price as the lowest British insulin shows that in the absence of a duty insulin could be sold at 33 per cent less than the present price. The minister expressed surprise that the Danish insulin was not made dearer by the duty but continued to be sold at the lowest British price. Elementary economics would have told him that there cannot be two prices for the same article in the same market and that if the Danish continued to be sold it would have to conform to the British price. All the sophistries cannot hide the fact that the insulin tax is a method of preventing the fall in price and is wanted for this purpose by the British manufacturers. It seems impossible to get from the minister the price at which insulin is sold in Denmark but according to the *Manchester Guardian* (the leading liberal paper in this country) 100 units could be bought there a few years ago for 23 cents.

Cysticercosis as a Cause of Epilepsy

At a meeting of the Royal Society of Tropical Medicine Col. W. P. MacArthur, consulting physician to the British army, showed that many cases of epilepsy were due to cysticercosis of the brain, a most important advance. The president of the society, Sir Leonard Rogers, described the paper as "historic." About 100 soldiers are discharged every year from the British army because of epilepsy. For many years occasional cases of cysticercosis complicated by epilepsy have been observed but their significance was missed until they were reviewed as a whole when it was noticed that all these cases were examples of heavy infestation with striking clinical signs and that there was no admixture of milder forms of the disease. Colonel MacArthur propounded the theory that the lighter grades of infestation were included in the heterogeneous group of 'epilepsy' mentioned. An inquiry to test this theory produced such strong confirmatory evidence that the war office about eighteen months ago ordered all cases of late developing epilepsy sent to the military hospital, Millbank, for special investigation. Colonel MacArthur has collected more than sixty military cases of cysticercosis and twenty have been diagnosed at the hospital during 1933. In the great majority of cases there was no evidence of infestation at any time with the adult *Taenia solium*. In the minority the symptoms began while the patient was under treatment for tapeworm or there was a latent period of several years between the complete expulsion of a worm and the development of clinical cysticercosis. There is always a larger number of palpable cysts than show themselves, for, when they eventually calcify and become visible in roentgenograms more may be seen in one arm than can be palpated in the whole body. The cysts may be detected in the muscles or subcutaneous tissue of any part of the body. Their size when

palpated in muscles, usually suggests that of a pea or hazelnut. In the brain the cysticercus becomes enclosed in a wall of sclerosed neuroglia. The death of the cysticercus is associated with increase in the quantity of fluid in the cysts which therefore becomes tense. Colonel MacArthur holds that while alive cysticerci usually are tolerated by the host, but after their death they act as irritants. Surrounding the dead cysticercus the brain tissues are seen to be undergoing active degenerative change with marked cellular response. In the brain, degenerating tissue may extend for at least 5 mm. beyond the cysticercus. After the death of the cysticercus, about three years is required for the scolex to calcify.

Of the nervous manifestations of cysticercosis epilepsy is the commonest. The fits may begin about the time the cysts are first detected or there may be a long latent period before the first fit. As the parasites may lodge in any part of the brain, any symptoms—motor, sensory or mental—of a focal lesion may be produced. The picture may be that of cerebral tumor, disseminated sclerosis or, if there is hyperinfestation, acute encephalitis.

The diagnosis of cysticercosis is usually missed because of failure to think of the disease. The history may be suggestive—the onset of fits in an adult without evidence of familial or personal epileptic taint. Residence abroad increases the probability of cysticercosis. The most helpful sign is the presence of palpable cysts, for which the patient should be examined from head to foot. But even in cases of heavy infestation of the muscles the parasites may not be evident. To demonstrate the parasite, a cyst should be excised. Roentgenography may disclose calcifying cysts.

No medicinal treatment is curative. The large number of parasites found in the brain and their wide distribution do not encourage resort to surgery. The successful removal of cerebral cysts has been reported, but before cure is certain time must be allowed for the other parasites in the brain to die, which may take years.

The Population Problem in India

Major General John Megaw, late director general of the Indian medical service and now president of the medical board India Office, gave a lecture to the East India Association on "Health and Population in India." He said that India was now the most populous country in the world, and in the last decennial period the increase was 10.6 per cent. Unless some unexpected check was applied there would be 400 millions of persons in India in 1941. He did not advocate any particular form of population control, whether celibacy, delayed marriage or contraception. Each individual and community must decide as to the special method of control acceptable to them. What he advocated strongly was that the people should be instructed in the hard facts which had to be faced and told how other countries had dealt with them. Remedial action ought to be prepared after a thorough investigation of the case by the best brains in England and India. The root cause of the trouble was ignorance, and the remedy was education. The difficulty would be to prepare a sound working scheme for instruction in life planning in an effective and acceptable manner. The cinema and broadcasting could be made instruments of revolutionizing the life of the Indian peoples in a few years.

In 1800 the population of Great Britain was 9 millions, growth for four of five centuries before that time having been extremely slow. Today it was between 40 and 42 millions—far too many—and yet it had been possible to produce out of this narrow environment what he believed to be the healthiest nation in the world. This had been accomplished not so much because of medical science as because of social circumstances which had been controlled by the government and by individual effort combined with education.

PARIS

Feb. 14, 1934

The Academy's Protests Against New Fiscal Rulings

To make up the deficit in the budget, parliament has introduced legislation designed to bring in more taxes and subjecting the liberal professions (physicians, lawyers, authors and artists) to closer surveillance. It is held that many members of these professions make insufficient declarations as to their taxable income since there is no adequate control. Parliament has ruled that all members of the liberal professions shall be compelled to keep a record of their daily receipts, which tax officers shall have the right to examine. The physicians immediately objected that they would be violating the right to privileged communication if they revealed the names of their clients. The law has therefore authorized the physician to use a figure in place of the name of a client, the figures being recorded in another book, kept secret, while the physician is compelled to give his clients receipts for the sums paid, only the accepted figure appearing on the receipts. The law thus modified has been passed by the two houses of parliament, which hopes to collect 400,000,000 francs (\$26,000,000), in this manner. The medical syndicates immediately raised energetic protests and emphasized that the substitution of a number for a name did not constitute sufficient protection of professional secrets. The Academy of Medicine took up the question. Professor Balthazard pointed out that an edict of parliament of 1750 still in force, formally declares that medicine is not a trade but a matter of science devotion and sacrifice. The Academy thereupon passed unanimously the following resolution: "The Academy wishing to join in the protests of the various medical groups against the new fiscal regulations imposed on the medical profession and recalling that physicians consider themselves bound absolutely by the right of privileged communication protests against the regulations that appear inapplicable and opposed to the spirit of social and human solidarity of the medical profession which cannot in any wise be compared with a commercial profession." Previously, Messieurs Vanvertz, Bezançon and Sirey had, in turn, shown that the law was not feasible. A physician summoned in an emergency to a patient cannot always carry his receipt book with him. The fees demanded of clients vary, in the option of the physician with their financial worth, so that controllers of the treasury would constantly be suspecting fraud.

Right of Injured Workmen to Refuse Operations

The question as to the right of a person who is injured in an occupational accident to refuse an intervention has been much discussed before the Society of Legal Medicine. The most competent members have been unable to reach an agreement on the subject. The fact is, the law is poorly worded and is susceptible of several interpretations. The society admits however that if an injured person whose condition might be improved by an intervention capable of diminishing his invalidity and consequently his benefits should refuse to accept such intervention he would be liable to suffer a reduction of his compensation. The society accepts such a reduction as only natural when during the course of treatment, the injured person is guilty of an inexcusable wrongful act. The cases are unfortunately numerous in which persons injured in an accident in order to secure larger compensation, voluntarily neglect their treatment. The insurance companies thus damaged use all their efforts to prove such fraudulent neglect. The courts in such cases have rendered contradictory decisions for the bad faith of the injured person is often difficult to prove. Hence the insurance companies desire a more precise wording of the law and the proper text of the law has been the subject of discussions before the Society of Legal Medicine. If the

approval of the society can be secured for the text of a law, it can be presented to parliament with such guarantees as would make it likely to be accepted, except by the socialists, who, as a matter of principle, always take the side of the workman. A preliminary text has been drawn up which reads as follows: 'If before the expiration of the time limits for revision (three years) the injured person refuses a benign operation to be performed, for example, under local anesthesia (ethyl chloride)—an operation that without risk would improve the functional state, the disability compensation shall be diminished in such proportion as the expert shall decide and the courts shall approve, if they deem it advisable. Mr. See approved these conclusions in general but remarked that in parliament it would no doubt be contended that the law of 1898 defines the apportioned compensations as a contract recompense. Mr. Huguency admitted that the abuses are much more frequent than is generally supposed but thought that a revision of the law is useless, since it already provides for a reduction of the benefits in case of inexcusable wrongful act on the part of the workman. Mr. Bourgeois held that the cost of the new operation should be paid by the employer together with half of the injured man's salary during treatment. Mr. Huguency responded that the costs would fall on the insurance companies, since they are benefited by having the compensation of the workman reduced. No definite conclusions have been reached as yet, owing to the difficulty of defining the expression "inexcusable wrongful act" of the workman.

Compulsory Antityphoid Vaccination

The Academy of Medicine, at the suggestion of Messieurs Vincent, Dopter and Leon Bernard, has adopted unanimously a resolution recommending that antityphoid and antiparatyphoid vaccination of all the personnel of the merchant marine be made compulsory. Cases of typhoid among this personnel are frequent, being in part the result of the impure water they drink, when on shore leave, in the small ports of France and foreign countries where hygiene supervision is defective. The incubation period being sometimes rather long the diagnosis by the ship's physician is often erroneous, and the sailors with a false diagnosis of gastric disorder with fever, often go to their homes in rural districts and create foci of typhoid.

BERLIN

Feb. 12, 1931

Control of Proposed Cancer Cures

The federal commission for the combating of cancer, in its new line-up, has expressed a willingness to test out the proposals that are made by physicians and laymen for the prevention, recognition and cure of cancerous diseases. This supervision will be carried out with the cooperation of the president of the federal bureau of health, the competent representative of the Prussian Medizinalverwaltung and the head of the department of pharmacology at the University of Berlin. All proposals, including those that appear at once to be useless, will at least be registered. Those that appear to have some possible value will be discussed by the commission as a whole, and such suggestions as seem worthy of serious consideration will be placed in the hands of experts. Remedies, the application of which, after a preliminary test, offers any possibilities of success will be tried out in a series of experiments in institutions, and during that time no information will be given out to the inventors of procedures. They will not be permitted to visit the institutions where the trials are being conducted. Before such research is begun, they must sign a statement to the effect that they will not make, either publicly or privately, any claims to rights or prerogatives with respect to publica-

tions, based on the fact that such trials are being made at the instance of the federal commission for the combating of cancer. They must agree that, following this research they will use solely the report, in unabbreviated and unemended form, of the federal commission. If the producers and inventors do not accept these conditions or do not adhere to them, or refuse to impart the information needed for the trials, the research will immediately be discontinued. In conducting such experiments, especial value will be attached to the securing of cancer cases that lend themselves to the drawing of comparisons. The hospital record card for tumor patients, which has been elaborated by the federal commission will be made the basis for the selection of suitable cases.

Fundamental Changes in German Hygiene

Before the Berlin Medical Society Professor Zeiss, the recently appointed hygienist of Berlin, delivered an address on 'The National Tasks of German Hygiene.' With the national revolution he pointed out the objectives and tasks of hygiene have been modified. In fact a fundamental change of views has occurred. Whereas under the former regime the main emphasis in hygiene was placed on social welfare and today the principles of demographic science which has of late, received new impulses must be more vigorously and actively applied. Thus hygiene more than ever has become the center for a number of related fields. The hygienist is especially fitted to become the exponent of true racial research. He is the natural diplomat of the physicians. The old conceptions of hygiene are outmoded. The old points of view of social hygiene must be abandoned. Fifty per cent of the program in this field must be omitted. Many branches of hygiene have, moreover, developed into well controlled special fields with their own technique for example street cleaning and sewage disposal. However the division of hygiene into special branches is to be condemned. It is important to consider and to carry on hygiene as an indivisible whole. Medical students must, however, become familiar with fields hitherto entirely neglected for example, with the problem of Germans living in scattered groups in foreign countries many of whom have for years waged a bitter fight for existence.

Zeiss called attention to the difficulties the scientist encounters today in endeavoring to explain all phenomena on the basis of the natural sciences. It has been known for some time that typhoid epidemics are not entirely dependent on the water. Even at the risk of being decried as a mystic Zeiss asserted that physicians should not reject astrology without further inquiry as having no scientific basis. Astronomical happenings should be studied as they have a possible connection with the appearance and disappearance of epidemics.

The Relation of Physiology and Physics

Addressing the Prussian Academy of Sciences Prof. Wilhelm Trendelenburg, of the University of Berlin, spoke on 'The Relation of Physiology to Physics.' This problem falls into three parts: the question of the share of physiology in the acquirement of a knowledge of the principles of physics, the question of the part played by physics in the sense perception and, in studying the problem from a deeper philosophical angle the question of the basic principles of research in both sciences and the compatibility of the 'world views' based on them.

The declarations of physics concern an "objective" external world, assumed hypothetically to exist, although adequate scientific proof of its existence cannot be furnished. But all knowledge of physical objects existing outside ourselves is derived through subjective sense perceptions, hence, to that extent, physics is, essentially, subordinated to physiology. It is of interest to the physicist to obtain a measure with which to test the subjectivity of the various perceptions. In all the

more delicate inquiries the senses, such as smell taste, touch, sense of warmth, sense of equilibrium and even hearing, must be eliminated, which leaves sight as the physical sense that is the organ of apprehension *par excellence*. Of the various functions of the eye, visual acuity functions most accurately. Accordingly, the physicist always seeks to reduce the establishment of differences of shades of light (for example, in the case of light absorption by solutions or the blackening of photographic plates) to coincidence or space measurements by the interposition of suitable apparatus. The brownian movement places a physical limitation on the sensitiveness of the various types of apparatus. The physiologic limitation is reached at the place where the points to be observed are no longer perceived to be separate and distinct. That is the case when on the retina, the space separating the images is considerably less than 0.001 mm, for then the stimuli no longer strike different retinal elements.

The second question concerns the physical theory of the various organs of sense. In recent years the mechanism of general nerve conductions has been studied by means of the Einthoven thread galvanometer. In observations on the acuity of smell it has been found that butterflies are capable of detecting at considerable distances the presence of almost unbelievably small concentrations of substances. Investigations on the smallest quantity of light that the human eye can detect following complete accommodation to the dark show that fifty photons suffices to produce a single light sensation. In continuous illumination, about three times as many photons per second are required. According to Noddack, a single light quantum to each of the retinal rods is sufficient for the production of light perception. Physicists have completely changed their views concerning the nature of light. How closely is physiology bound to the changing status of physical research? Would a "crisis" in physics bring about a crisis in physiology? Trendelenburg holds that, in spite of the recent upheavals in physics, one cannot speak of a crisis in that science but only of the overthrow of certain theories. That there should be a succession of theories lies in the nature of scientific research. One must take the attitude that all one can demand of a theory is that it shall be reconcilable to all ascertained facts that come within its scope. Physiology needs not to reestablish its claims to its factual acquisitions but needs only to reinterpret them.

From the lofty pinnacle of the philosopher, therefore, one views the following remarkable prospect. Physics can obtain no knowledge that is not colored, as it were by physiology, while physiology cannot, on its own account, make any final pronouncements without consulting physics. Will the two theoretical structures support each other, or can problems arise that will effect the downfall of both? Such a menace lies in the psychophysical problem, which takes a position before all science based on observations and is independent of it. Research in the natural sciences can reveal only physical facts. The specific character of conscious experience on the 'inside' of the physiologic processes is not accessible to such research.

Exhibits by the Public Library

The Badische Landesbibliothek in Karlsruhe makes a practice of organizing instructive exhibits. Just now the library is coming to the aid of the public health service. Under the heading "Literature on Health Culture" numerous manuscripts, printed works and pictures dating from the ninth to the nineteenth century have been combined in an exhibit. Of particular interest are the illustrations found in books and manuscripts produced about the year 1000 in the Reichenau cloister on Lake Constance. Then there are old prints that shed light on the development of anatomy surgery and education of the people in hygiene and health legislation also works of Frank and Mai, Baden's pioneers in the field of public health culture.

AUSTRALIA

(From Our Regular Correspondent)

Feb 20, 1934

Australasian Medical Congress

The fourth session of the Australasian Medical Congress (British Medical Association) was held at Hobart, Tasmania, the southernmost city in Australia.

CANCER RESEARCH AND TREATMENT

In 1900 the death rate of cancer in Australia was 57 per hundred thousand persons. In 1931 it was 105. For a time it was thought that this increase was fictitious, being the result of closer study and more accurate diagnosis. The time for this theory, true as it possibly was between 1900 and, say, 1910 has passed. In a scattered population such as exists in Australia, the distribution of radon is more convenient than the use of the element itself. Other advantages are that the patient under treatment by gaseous radium can leave the hospital as soon as the application is made. The danger of loss is negligible. The radium bomb has been definitely considered uneconomic, conditions requiring the bomb can be as effectively treated by high voltage roentgen therapy. Great economy is achieved, as all available energy from the radium is collected and used, the radium is never idle, many more patients can be treated, and the needles can be bent and prepared according to the specification of the surgeon. During the last seven years a sum of £373,165 has been allotted for the cancer campaign by the commonwealth and state governments and other state organizations. A total of approximately 12 Gm of radium has been put into use. Cancer clinics have been instituted at eighteen large metropolitan hospitals as well as a number of extrametropolitan hospitals. In the four years since treatment by radium was begun on an organized basis, radium has been used in the treatment of approximately 10,000 cases of cancer. The number of cases treated by means of x-rays or surgery or by other methods in which radium has had no part is not known.

As to the success achieved on the one hand the death rate from all forms of cancer has increased from 96 to 105 per hundred thousand in the last four years. On the other hand, although sufficient time has not elapsed to enable figures to be given in terms of the five-year series, the results of treatment are definitely improving, and the mortality statistics for 1931, based on the estimated population in the age groups for that year, showed a decline in cancer mortality in all such groups under 65 years of age.

Dr L J Clendinnen of Melbourne discussed the present status of radium in the treatment of cancer. In cancer of the tongue he said, radium treatment has been disappointing. There is an immediate response to its treatment with radium, but the growth soon recurs nearby. The use of radium has displaced surgical operation in the treatment of lip cancer, because radium is able to deal with the infiltrating border of the growth in a way that is not possible by surgical operation. In cancer of the breast, Dr Clendinnen quoted figures of 218 patients treated in Melbourne in the last five years and showed that, of the patients in the inoperable stage treated by operation, 100 per cent had growths in adjacent areas within six months of the operation. Among the corresponding class treated with radium the local recurrence rate was 13 per cent. He quoted these figures in support of the contention that cancer of the breast, incompletely removed would recur more quickly than if it was treated by radium. Finally he referred to cancer of the uterus. Every patient who had sought relief from the condition he said, had the disease in an advanced stage. He made a plea for the education of the public in the early signs and symptoms of cancer of the uterus so that patients may

apply for treatment while there is some hope of its being successful

The pathologic aspect of the cancer problem was discussed by Dr J V Duhig of Brisbane, who said that until recently the cancer pathologist did not see much beyond the horizon of fixed tissue histology. Today no review of the pathology of cancer could be even moderately complete without a survey of the work of the experimental cytologist, pathologist and biochemist, and latterly the physicist.

Dr E H Molesworth of the University of Sydney, who read a paper on the status of roentgen therapy in the treatment of cancer, said there was a strong tendency on the part of many persons to regard roentgen treatment and radium treatment as separate entities. In reality there was exactly the same difference between the two as there was between treatment by radium implanted in the tissues surrounding the growth and that by radium at a distance. Ultimately only economic considerations would determine whether a roentgen tube radium at a few centimeters distance, or a radium bomb would be employed for a tumor in any given situation.

In a discussion on the surgical treatment of cancer, Dr F P Sandes of Sydney said that cancer surgery had become a definite specialized branch of the healing art and that the time was long past when cancer should be regarded solely as a surgical disease. Cancer treatment was no longer individualistic but a matter for team work. The surgeon should be at the head of the team, but he would not be able to occupy this position unless he trained himself to fill it. In reference to work of cancer immunology carried out on animals he said it was not too much to hope that in the near future the results obtained might be made applicable to man.

An interesting observation was made by Professor Chapman of Sydney, who investigated the cancer incidence among road workers who had been handling tar for the past thirty years. He found that cancer was less common than in corresponding age groups of the general population.

Introduction of Disease by Airplane

The development of airplane communications with Australia, traversing, as they do, the areas of endemic disease in the 'East, has necessitated the provision of special quarantine arrangements in Northern Australia. With the transit time reduced to about five days from these endemic areas, a real danger has been introduced. In consultation with other countries, regulations are now being framed whereby all persons arriving in Australia from the north will be required to have been vaccinated recently against smallpox. Otherwise they will be vaccinated at Darwin. Persons suspected of carrying other dangerous diseases will be detained at the new quarantine station that is to be built at Darwin. Owing to the rarity of smallpox in Australia it is felt that the people are protected by effective vaccination. A serious outbreak in any of the thickly populated districts would have serious consequences. The England-Australia air mail will traverse some of the danger areas of the world where smallpox, cholera and yellow fever are rife. Strict measures must be taken to protect Australia from this menace. A bacteriologic and diagnostic laboratory is also being constructed at that center, which is the first port of call of airplanes arriving in Australia. Tropical disease is receiving increased attention in Australia today. Dr R W Cilento has been appointed research officer in Tropical Diseases at the School of Tropical Medicine at Sydney.

Infant and Maternal Welfare in New Zealand

Another low record for infant mortality, 32.15 per thousand live births, has been established for New Zealand. This is also a world record. The birth rate was also the lowest on record. The maternal figures are not so stimulating. The

total puerperal mortality rate has remained practically stationary since 1927. The mortality from the toxemias has risen slightly, that from the 'accidents' of pregnancy has risen considerably, while the mortality from septic abortion has risen alarmingly. On the other hand the mortality from puerperal sepsis, excluding septic abortion, shows a most gratifying fall from 2.01 in 1927 to 0.68 in 1931. The rising returns of mortality from septic abortion are giving the New Zealand authorities great concern. Out of twenty-nine fatal cases that were officially investigated in the year 1931 twenty-six occurred in married women, which indicates that the incentives to abortion arise mainly from social and economic circumstances and not from loose living. Here is one of the most difficult problems in the whole field of maternal mortality.

During the past ten years a generous provision of hospital beds for midwifery has been made and it now amounts to one bed per thousand of the white population. During the year under review, 70 per cent of the total births took place in hospitals. It is interesting to note that there were far fewer instrumental deliveries; the forceps rate having fallen from 14.5 per cent in 1927 to 9.15 per cent in 1931. Hospital deliveries have also enabled a far wider application of the principles of surgical asepsis. It is a world-wide problem that the rising sepsis mortality from criminal abortion should counteract the improvement that is gained in the mortality from sepsis following labor. There is a trend of unofficial opinion in these parts of the world which tends toward the continental outlook on abortion.

Tetanus from Catgut

Considerable disquietude has been occasioned by the occurrence in New South Wales during the past twelve months of four cases of tetanus following surgical operations in which catgut was used. The usual method of attempted sterilization adopted is by means of red mercuric iodide and alcohol. Samples of catgut so treated have been shown bacteriologically not to be sterile and tetanus bacilli have been obtained from cultures.

Typhoid from Oysters

An epidemic of twenty-four cases of typhoid is in progress in Brisbane. Investigations by the health department showed that the patients were all supplied with oysters by one vendor who obtained them from beds that were in close proximity to the main sewer into the bay. Typhoid bacilli were isolated from samples of oysters taken from this bed.

Marriages

- EUGENE JOSEPH LOY, Petersburg, Ky., to Miss Alberta N. Sheldon of Dupont, Ind., at Lexington, Ky., Nov. 22, 1933.
JEREMIAH ROBERT JOHNSON to Miss Lois Ellis, both of Ramsey, N. C., at Chesterfield S. C., Dec. 23, 1933.
CHESTER A. KISSINGER to Mrs. Edward Higgins, both of Milwaukee, at Woodstock, Ill., February 17.
WENDEL J. BURKETT PITMAN, N. J., to Miss Anita L. Sprigman of Woodbury, February 17.
JULIUS HOWARD STOKES McBEE, S. C., to Miss Helen Rhoad of Strawberry, Dec. 28, 1933.
CARLOS IZLAP GREIN to Miss Kittie Albergotti, both of Orangeburg S. C., January 14.
ROY M. LANIER Brownsville, Tenn., to Miss Mildred Jones of Memphis, February 16.
HARRY GREENSTEIN to Miss Ethel Rose Simon, both of Chicago, February 1.
ARTHUR KARL KOFF to Miss Dorothy Hess, both of Baltimore, January 17.
JAMES E. JOSES to Miss Gladys Haws, both of Indianapolis, January 25.

Deaths

Ernest Scott • Columbus, Ohio, Ohio Medical University, Columbus, 1900, professor of pathology, Ohio State University College of Medicine since 1915, and assistant professor of veterinary pathology, 1908-1915 professor of histology, 1903-1904, and professor of pathology, 1904-1910, at his alma mater, professor of pathology, Starling-Ohio Medical College, 1908-1915, member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists, bacteriologist to the city board of health, 1904-1908 on the staff of the Columbus State Hospital and pathologist to the University Hospital, aged 58, died, March 5, at his home in Westerville, of coronary thrombosis

William A. Frontz • Baltimore, Johns Hopkins University School of Medicine, Baltimore, 1911, member of the American Association of Genito Urinary Surgeons and the American Urological Association, associate professor of urology at his alma mater, served during the World War, aged 48 associate editor of the *Journal of Urology*, visiting urologist to the Sinai Hospital and assistant visiting urologist to the Johns Hopkins Hospital, where he died, March 23, of heart disease

Maurice Packard • New York, Columbia University College of Physicians and Surgeons, New York, 1900, on the staffs of the Gouverneur Hospital, Hospital for Joint Diseases, Broad Street Hospital and the Jewish Maternity Hospital, New York, and the Home for the Aged Infirm, Yonkers, aged 57, died, March 15 of heart disease, while en route to the Pan American Medical Congress

William Ralph Campbell • Major, M. C., U. S. Army, Omaha, Neb., University of Colorado School of Medicine, Denver, 1916, served during the World War, entered the medical corps of the U. S. Army as a first lieutenant in 1918 and in 1929 was made a major, aged 44, died March 9, in the Station Hospital, U. S. Army, Fort Leavenworth, Kansas

Norman Smith Starr, Oklahoma City, University of Michigan Homeopathic Medical School, Ann Arbor, 1915, member of the Associated Anesthetists of the United States and Canada, served during the World War, aged 45 died, January 30, in the Veterans' Department of the Oklahoma State Hospital, Norman

Luther Franklin Robinson, Ullin Ill. Hospital College of Medicine, Louisville, Ky., 1889, member of the Illinois State Medical Society, past president and secretary of the Pulaski County Medical Society, for fifteen years bank president formerly mayor, aged 82, died, February 15, of arteriosclerosis and acute nephritis

James Walter Reese, Cleveland Ohio State University College of Homeopathic Medicine, Columbus, 1915 served during the World War, formerly member of the city health department, aged 41, died, March 2, in the U. S. Marine Hospital, of acute meningitis, chronic sinusitis and carcinoma of the left antrum

Lewis Harry Adler, Jr. • Philadelphia, University of Pennsylvania School of Medicine, Philadelphia 1888 member of the House of Delegates of the American Medical Association in 1911, fellow of the American College of Surgeons, on the staff of the Charity Hospital, aged 69 died, March 5, of heart disease

John Marion Wolfe, Jacksonville, Ill., Barnes Medical College, St. Louis, 1898, member of the Illinois State Medical Society past president of the board of education on the staffs of Our Saviors Hospital and the Passavant Memorial Hospital, aged 62, died, February 23, of toxemia and nephritis

William P. S. Henry, Everett, Pa., University of Pennsylvania School of Medicine, Philadelphia 1882 member of the Medical Society of the State of Pennsylvania past president of the Bedford County Medical Society served during the World War, aged 77 died, February 17 of pneumonia

Vito Witting • Urbana Ill., Royal University of Florence Faculty of Medicine and Surgery Florence Italy 1926 in 1928 vice secretary to the Italian Congress of Medical Radiology aged 30, on the staff of the Carle Memorial Hospital where he died February 11 of lymphatic leukemia

Robert Joseph Shea, New York Cornell University Medical College, New York 1914 member of the Medical Society of the State of New York, fellow of the American College of Surgeons on the staff of St. Elizabeth's Hospital aged 43 died, February 15 of coronary sclerosis

Alexander Chace Sanford, Newport, R. I., Bellevue Hospital Medical College, New York, 1898, member of the Rhode Island Medical Society secretary of the Newport County Medical Society, aged 59, visiting physician to the Newport Hospital, where he died, February 2

William Farquhar Bacon • York Pa., Bellevue Hospital Medical College New York, 1882, member of the House of Delegates of the American Medical Association in 1908, and from 1916 to 1922, on the staff of the York Hospital, aged 74 died, February 15, of heart disease

Angell Sigvart Hoiland • Minneapolis, University of Minnesota Medical School, Minneapolis, 1910, fellow of the American College of Surgeons, aged 49, on the staff of the Lutheran Deaconess Home and Hospital, where he died, February 22, of valvular heart disease

Thomas Francis Healey, Stamford, Conn., Long Island College Hospital, Brooklyn, 1908 member of the Connecticut State Medical Society, served during the World War aged 51 died suddenly, March 16, in the Stamford Hospital, of perforated duodenal ulcer and peritonitis

Henry Seaton Hutchison, Toronto, Ont., Canada, University of Toronto Faculty of Medicine 1900, assistant professor of medicine at his alma mater, physician in charge of the outpatient department of the Toronto General Hospital, aged 54 died, January 6

James E. Mason, Stettler, Alta., Canada, Western University Faculty of Medicine, London, Ont., 1914, fellow of the American College of Surgeons, ship surgeon on the S. S. *Niagara*, aged 48, died, in January, on board ship on the Pacific Ocean

Elmer Ellsworth Vorhies, Cambridge, Ohio, Starling Medical College, Columbus, 1893, member of the Ohio State Medical Association, formerly county coroner and state senator, aged 68, died, February 11, in the Swan Hospital, of heart disease

Charles Tracie Henderson, Gouverneur, N. Y. Syracuse (N. Y.) University College of Medicine, 1911, member of the Medical Society of the State of New York, on the staff of the Stephen B. Van Duzee Hospital, aged 54 died, February 7

Henry A. Brierley, Pccuhar, Mo. University Medical College of Kansas City, Mo., 1895, member of the Missouri State Medical Association aged 65 died, March 1, in the Wesley Hospital, Kansas City, Mo. of coronary thrombosis

Herbert Halsey Hurd • Chippewa Falls, Wis. Rush Medical College, Chicago, 1878 past president of the Chippewa County Medical Society aged 81, died, March 9, in St. Joseph's Hospital, as the result of a fractured hip received in a fall

La Vern I. Rogers • Galesburg, Mich. University of Michigan Medical School, Ann Arbor, 1907 aged 51, on the staffs of the Borgess Hospital and the Bronson Hospital, Kalamazoo, where he died, February 12, of pneumonia

Albert E. Hoff • North Bend Neb. Central Medical College of St. Joseph Mo. 1898, fellow of the American College of Physicians, past president of the Dodge County Medical Society, aged 63, died, January 27, of heart disease

Alfred Jesse Stewart, Ontario, Calif. Hahnemann Medical College and Hospital, Chicago, 1896 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906, aged 65, died, January 13

John Wesley Robinson, Grand Rapids, Mich. Illinois Medical College, Chicago 1900, on the staff of the Michigan Soldiers' Home Hospital, aged 62 died, March 7, in the Butterworth Hospital of cerebral hemorrhage

Manly Eugene Siler, Mercer Tenn., Memphis Hospital Medical College, 1907 member of the Tennessee State Medical Association for many years president of the school board, aged 51, died, February 12, of heart disease

Henry Wade, Starksboro, Vt. University of Vermont College of Medicine, Burlington, 1883, member of the Vermont State Medical Society, health officer, aged 81, died, January 2, of injuries received in an automobile accident

Carlton Victor Wilder, Atlantic, Iowa, Hahnemann Medical College and Hospital, Chicago 1882, member of the Iowa State Medical Society on the staff of the Atlantic Hospital, aged 82, died February 13 of heart disease

Algernon Winston Walden, Owingsville Ky., College of Physicians and Surgeons Baltimore 1883 county health officer at one time member of the state board of health, aged 77, died, February 28 of cerebral hemorrhage

Le Roy Boyd, Birmingham Ala., Medical College of Alabama Mobile 1887 member of the Medical Association of the State of Alabama aged 70 died, February 21 of angina pectoris and arteriosclerosis

Campbell Ford, San Francisco University of California Medical Department 1891, member of the California Medical Association, died 69, died, February 11, of an incised wound of the throat presumably self inflicted

Edward Evan Sargent & Le Roy, III, Miami Medical College, Cincinnati, 1893 for twelve years president of the school board, aged 65 died February 20, in the Brooklyn Hospital, Normal, of agranulocytosis

Arthur E Walker & Anthony Kan Medical College of Indiana, Indianapolis 1892, past president and secretary of the Harper County Medical Society, aged 73 died, February 5, of cerebral hemorrhage

Osmond Nason Hoyt, Long Beach Calif., Hahnemann Medical College and Hospital Chicago 1879 formerly superintendent of the state board of health of South Dakota aged 90 died Dec 30, 1933

George L Morgenthau & Chicago Dartmouth Medical School Hanover, N H 1888 for many years on the staff of the Michael Reese Hospital aged 71 died March 21 of eczema and morphine poisoning

George Dill Rowe, 1st Providence R I Medical School of Maine, Portland 1889 member of the Maine Medical Association aged 67, died March 3 when he was unable to escape from a burning hotel

Octavus P Larpe & Philadelphia Medico-Chirurgical College of Philadelphia 1898 aged 65 died March 14 in the Temple University Hospital, of cellulitis of the neck and septicemia

Oscar O Blakeslee, Cincinnati Ohio College of Physicians and Surgeons, Baltimore 1882 city health officer aged 80, died February 28 in the Brown Memorial Hospital of pneumonia

Birt B Reeder, Clarksville Fla Georgia College of Eclectic Medicine and Surgery Atlanta 1910, aged 54 died March 2, in a hospital at Dothan Ala of carcinoma of the stomach

Joseph Lemuel Campbell, Bristol Penn Chattanooga Medical College 1902 member of the Tennessee State Medical Association aged 58 died, February 17 of myocardial insufficiency

Alexander Abraham Aron, Philadelphia, University of Pennsylvania School of Medicine Philadelphia 1906 aged 50, died March 5, in the Mount Sinai Hospital, of cardiovascular disease

Bertha Caroline Downing Kennettunk Maine Women's Medical College of Pennsylvania Philadelphia 1896 aged 72, died, Nov 21, 1933, of chronic nephritis and intestinal hemorrhage

George Munson Vindegrift, New York University of the City of New York Medical Department 1879 aged 80, died suddenly, February 10 in Snow Hill Md of heart disease

Edward Sutherland Winbiger & Alexis, III Rush Medical College, Chicago 1893 for many years member of the school board, aged 66, died, February 12, of hepatic cirrhosis

James Mitchell Hartley, Hollywood Fla Atlanta Medical College, 1915 member of the Florida Medical Association aged 45, died, February 19 of a self inflicted bullet wound

Albert Asa Cannaday & Roanoke Va University of the City of New York Medical Department, 1888, aged 70, died, February 22, in the Shenandoah Hospital, of Ludwig's angina

Thomas Emmett McDermott, Minneapolis, Chicago Medical College, 1883, aged 77, died, February 20, in St Barnabas Hospital, of uremia and carcinoma of the prostate

Mat Marshall McRee, Dallas, Texas, Vanderbilt University School of Medicine, Nashville Tenn, 1901, aged 57, was found dead, February 26, of a self inflicted bullet wound

George M Stillman, Argyle, N Y, Albany Medical College, 1885, formerly county coroner, aged 75 died, February 24, of arteriosclerosis and chronic myocarditis

Frederick Kellogg Hollister, East Hampton, N Y New York Homeopathic Medical College and Hospital, 1895, aged 64 died, February 4, of carcinoma of the larynx

James Willard Bazell & Winslow, Ariz, University of Louisville (Ky) School of Medicine, 1909, formerly health officer of Winslow, aged 52, died, Dec 22, 1933

Lamont B Smith, Youngstown, Ohio, Cleveland Homeopathic Medical College, 1898, aged 56, died, February 12, in St Elizabeth's Hospital, of cardiorenal disease

James Rutherford Bingham & New York, Trinity Medical College Toronto, Ont, Canada, 1893, aged 71, died, March 9, in the Doctors Hospital of pneumonia

Thomas Sheldon Taylor, Schellsburg, Pa, University of Louisville (Ky) School of Medicine, 1907, aged 47, died, February 10 in Miami Fla, of acute nephritis

Samuel Addison Roberts, Salem, Ind., University of Louisville (Ky) School of Medicine, 1882, county health officer aged 73, died March 2, of nephritis

S Hilton Baker, Killbuck Ohio, Medical College of Ohio Cincinnati 1887, member of the Ohio State Medical Association aged 69, died March 8 of nephritis

Minnie Dell Baker, Nashville, Mich, Hahnemann Medical College and Hospital Chicago 1891, aged 75, died, in February, at Grand Rapids of myocarditis

Oscar Lee Wilson, Rushville Neb Medical College of Indiana, Indianapolis 1879, aged 76, died, January 20, of chronic myocarditis and arteriosclerosis

Parker Fiske Wesley, Haviland, Kan, Hospital College of Medicine Louisville Ky, 1905 aged 50, died February 19, in a hospital at Pratt of acute nephritis

George W Richardson, Dundee, Mich, University of Buffalo School of Medicine 1878, also a pharmacist, aged 81, died March 7, of cerebral hemorrhage

Henry Marcellus Johns, Waco, Texas University of Tennessee Medical Department Nashville, 1895, aged 70, died, January 31 of cerebral hemorrhage

Jeremiah R Sturtevant, Theresa N Y Albany Medical College 1872, aged 86, died, January 19, of chronic myocarditis and concussion of the brain

Robert Lincoln Watkins & New York University of the City of New York Medical Department, 1887, aged 70, died, February 25 of lobar pneumonia

Frederick Graham Brien, Elphinstone, Manit Canada, University of Manitoba Faculty of Medicine, Halifax 1894, aged 71 died Dec 30 1933

Basil Dennis Spalding, Richmond Va, University of Maryland School of Medicine, Baltimore 1891 aged 70, died February 17, of myocarditis

John Borsman Rone, Oklahoma City University of Louisville (Ky) School of Medicine 1893, aged 71, died suddenly February 8, of myocarditis

William Lockwood West New Martins, Ohio, Jefferson Medical College of Philadelphia, 1874 aged 83, died in February, of pneumonia

Edward Payson Ward Whitmore Lake, Mich Chicago Medical College 1887 aged 71, was found dead, February 16, of valvular heart disease

Frank M Wright, Indianapolis Indiana Eclectic Medical College Indianapolis 1889 aged 75, died February 14 of pulmonary tuberculosis

Lewis F Hammonds, Dunnville Ky, University of Louisville School of Medicine 1897, aged 65, died, February 21 of cerebral hemorrhage

William Clark Watson & Bridgeport Conn Long Island College Hospital Brooklyn, 1897, aged 60, died January 22, of heart disease

Austin Roy Harman Lubec, Maine Jefferson Medical College of Philadelphia, 1896, aged 61, died, January 22, of angina pectoris

William Arnold Christian & Chicago Cincinnati College of Medicine and Surgery, 1899, aged 62 died, February 4, of brain tumor

Joseph L Smith, Hoagland, Ind, Eclectic Medical Institute Cincinnati, 1878, aged 82, died, February 22, of chronic myocarditis

Emil C Schoene, Milwaukee Chicago Physio Medical College, 1895, aged 70, died suddenly, February 13, of coronary sclerosis

John Albert Christilaw, Winnipeg, Manit, Canada Manitoba Medical College, Winnipeg, 1914, aged 61, died, January 23

Cyrus Henry Cutter, Aurora Ill, Rush Medical College, Chicago, 1881, aged 76 died, March 4, of coronary sclerosis

Henry Rosenblith, Chicago Illinois Medical College, Chicago, 1900, aged 63 died, February 14, of coronary thrombosis

Daniel Webster Shier, Weston, Ont, Canada, Trinity Medical College, Toronto, 1895, aged 65, died, January 8

Aaron G Rogers & Parker, Ind (licensed, Indiana, 1897), aged 84, died, February 9, of carcinoma of the prostate

Correspondence

TREATMENT OF AMEBIASIS

To the Editor —There is a communication in THE JOURNAL, Dec 2, 1933, pages 1819-1820, signed by Dr J C Geiger and others, with respect to the various drugs used in the treatment of human amebiasis due to infestation with *Endamoeba histolytica*. In this, reference is made on page 1820, column 2, paragraphs 2 and 4, to the use of "bismuth subcarbonate in massive doses" in the treatment of this infestation, and a paper by the late Dr W E Deeks and myself in the *American Journal of Tropical Medicine* (5 97 [March] 1925) is mentioned. Kindly permit me to correct an error here.

It is bismuth subnitrate, not the subcarbonate, that was first used in this manner by Dr Deeks. I do not have at hand this copy of the *American Journal of Tropical Medicine* and my supply of reprints has been exhausted. I am referring, however, to the original paper which was entitled "The Etiology, Symptomatology and Treatment of Intestinal Amebiasis" by Dr Deeks and myself. This appeared in the Proceedings of the International Conference on Health Problems in Tropical America, published by the United Fruit Company in 1924, pages 271-308.

I make this correction because Dr Deeks and myself at first and myself later tried bismuth subcarbonate in massive doses and found that the results were not as good as when the subnitrate was given. The dose is a heaping teaspoonful well mixed in milk or water from three to five times a day.

I have used this treatment since it was first advocated by Deeks and Shaw in the *Medical Record* Nov 13, 1909.

In acute dysentery its use should be supplemented by emetine when this can be given under experienced supervision. It has been known for many years and reported that emetine is a dangerous drug and that its toxic effects cannot be predicted. These may come on after the first dose or later at any time during the course of treatment. It is particularly dangerous in patients with any form of myocardial degeneration or weakness. At present I would not advocate the use of bismuth subnitrate in the acute fulminating types of amebic dysentery, as I believe that valuable time might be lost. These cases are in my opinion best treated by a wide open cecostomy and thorough irrigations through the cecostomy and through the rectum as well. This method was used by Dr A B Herrick when he was chief of the surgical clinic in the old Ancon Hospital, during the construction days of the Panama Canal, before Rogers had reintroduced emetine and it was found to be very effective in the acute fulminating types and also in the chronic types that did not yield to other treatment.

In the milder types of amebic dysentery, however, and especially in the chronic forms of infestation without diarrhea and dysentery I have found bismuth subnitrate very useful indeed. It should be given over a period of two or three months and I have never seen any harm result, except in two cases in which the bismuth was contaminated with antimony and these were long ago.

Several theories have been advanced as to why bismuth subnitrate is efficacious and these were discussed by Dr Deeks and myself in the paper referred to. However at this time I believe it is efficacious solely as an astringent. Very likely it also cleans out the amebas living in the lumen of the bowel and prevents these from entering the tissues.

In a paper entitled *Human Amoebiasis Due to Infection with Entamoeba Histolytica* (*Ann Trop Med & Parasitol* August 1928) I stated that I believe if the ulcers and other pathological lesions of the large intestine can be caused to heal the amebas in the tissues will disappear and I am still of this belief otherwise there would be no permanent cures.

I should not like to be understood as claiming that bismuth subnitrate is a true specific and always cures the infestation, since I have used other drugs frequently in conjunction with it, but for me it is a sheet anchor.

In addition to the articles you mention that may be consulted with respect to amebic dysentery in the footnote to your review of this subject in THE JOURNAL, Nov 18 1933, page 1639, permit me to suggest "The Amoebae Living in Man," by Clifford Dobell, published in 1919 by William Wood & Co., New York, and the chapter on the "Entamoebae of Man," in "Protozoology," by C M Wenyon, volume I, page 84, also published in 1926 by William Wood & Co. Any one interested in the study of human amebiasis will find these authoritative and instructive.

In several communications received from friends at home they have mentioned the difficulty they are encountering in using the wet fixation and Heidenhain's iron hematoxylin method of staining. I had much trouble years ago in learning to use this method correctly. In the *Annals of Tropical Medicine and Parasitology* 8 133-320 (July) 1914, is an article of mine entitled "A Study of the Entamoebae of Man in the Panama Canal Zone." In this article I put down all the troubles which I encountered and endeavored to describe in detail the various methods of wet fixation and staining which were in use at that time and are still useful today. Dr R B H Gradwohl described wet fixation and staining in THE JOURNAL Jan 6, 1934, page 65, which covers most of the essential points. I myself should advise the use of slides and not of cover glasses, as the latter are difficult and very troublesome to handle.

I have found that fixation in a modified Schaudinn's fluid, consisting of two parts of physiologic solution of sodium chloride saturated with corrosive mercuric chloride and one part of 96 per cent or absolute ethyl alcohol, plus the addition of from 25 to 5 per cent of glacial acetic acid, has given me better results than the aqueous solution saturated with corrosive mercuric chloride, without the acetic acid. The weaker acetic acid solution is better for the delicate trophozoites in acute and subacute dysentery, and the stronger solution gives better fixation for cysts. I believe that from twenty to sixty minutes is too long a time for fixation of thin stool smears since most authorities find that from five to ten minutes is ample. I prefer to fix at room temperature, as the heated fixing solutions produce artefacts, as has been pointed out by Leland Cleveland.

In step 6 of his article, Dr Gradwohl does not mention that the preparations should be thoroughly rinsed after mordanting. It is very important that this be done, two separate containers holding at least 1 liter of water each being used. If the preparations are not thoroughly rinsed, an excess of the mordant is carried over into the hematoxylin solution, making decolorization difficult, and the amebas are likely to appear a dirty yellow with indistinct nuclei instead of showing a clear gray cytoplasm with sharply defined and clear cut black or deep purple nuclei.

Also in step 6 Dr Gradwohl has omitted to state that the hematoxylin solution should be diluted one half with distilled water before using. The 1 per cent stock solution is too strong. It is not necessary though advisable to allow the solution to ripen for four weeks before using. If it is thoroughly aerated by allowing a current of air to pass through it over night it will be ready for use in the morning. The diluted solution should be filtered after use into a clean bottle. Later this filtered diluted solution should be used with an equal part of the original stock solution diluted one half then filtered again into the second bottle and so on until the original stock solution is used up when there will be two bottles of stain. These can be used undiluted repeatedly and they improve with use until

the hematoxylin is finally precipitated. This can be told by adding a few drops of the stain to a test tube half full of tap water. If the resulting color is yellow or green, the stain is no longer useful, if the color is blue or violet, the stain is still good. Only a good quality of distilled water should be used for diluting the stool solution, tap water or alkaline water will precipitate the hematoxylin or, rather, the hematin, which is the active staining principle. The staining solutions should be kept in brown glass bottles, away from the light.

Free living amebae can be obtained easily in the zoological laboratories of most of our universities at home. If these are used for practice the necessary skill and judgment can be obtained by those unfamiliar with the method more readily than by using stool smears in the beginning. Wet fixation and staining is a tiresome method but I do not know of any other that will give such accurate results in distinguishing the five species of amebae found in the stools.

WILLIAM M. JAMES, M.D., Panama, R. P.

DENTAL CARIES

To the Editor—I have read with interest the editorial on dental caries published in *The Journal* of February 17 and I would like to submit the following comment.

There have appeared recently in several periodicals (including *Science* 78:419 [Nov.] 1933) articles by Bunting and his associates in the University of Michigan which claim emphatically and with an air of finality that the etiology of dental caries has been fully established by them and that *Lactobacillus acidophilus* is the active causative agent.

Such an assertion if based on adequate scientific evidence would in the last analysis imply three things: (1) that caries is caused by a specific organism, (2) that the organism is *Lactobacillus* and (3) that the *Lactobacillus* is unequivocally *L. acidophilus*.

1. The bacterial etiology concept still lacks general support. This is revealed by a general review of papers appearing in dental journals and by unpublished statements of investigators of dental pathology. So-called proof of bacterial etiology relationship appears still to be far from complete.

2. Researches during the past six or seven years have impressed on me the numerical importance of high acid-producing streptococci in caries and noncaries mouths compared with *Lactobacilli*. By following the quantitative plating method devised and recommended by Rodriguez (*J. Am. Dental A.* 17:1711 [Sept.] 1930) my associates and I demonstrated the occurrence of millions of high acid-producing bacteria per cubic centimeter of saliva but these proved, on close observation to be streptococci essentially, instead of *Lactobacilli*, as featured by Rodriguez and later by Mrs. Hadley. If bacterial acids do play an important role in dental caries is it not plausible that streptococci should be even stronger contributing factors in caries production than *Lactobacilli*?

3. In spite of certain isolated claims to the contrary, the *Lactobacilli* of the mouth and tooth cavities are of definite "oral" type and differ in several important respects from the "intestinal" types, including *L. acidophilus*. Some of these fundamental differences were stressed by me (*Jale J. Biol. & Med.* 4:485 [March] 1932). Morishita (*J. Bact.* 18:181 [Sept.] 1929) recognized the aciduric organisms of the mouth and intestine as being different. Researches of the past two years have strongly confirmed my belief in the diversity of the two general types.

Some writers claim to have shown that mouth *Lactobacilli* may be dissociated into rough forms which resemble *L. acidophilus* of the intestine. Their observations were incomplete and not convincing. More recently, Weinstein, Anderson and Rettger (*J. Dental Research*, August 1933) failed in attempts

to derive one type from another. Dissociation was effected to a certain point but could not be carried further.

I do not wish to detract from the work of those whose claims are so strongly affirmed with my own. I take this occasion, however, to protest against the high powered claims made and reiterated again and again by these investigators. In the present limited state of knowledge regarding the etiology of caries conservatism is the safer course. Little can be gained for example, by referring to the mouth *Lactobacilli* as *L. acidophilus*.

LOCAL ANESTHETICS IN ARTICULAR PAIN

To the Editor—The recent reply of Dr. J. C. Weinstein (*The Journal* of March 3 p. 714) to the criticism (January 13 p. 145) of the use of local anesthetics in articular pain (Paris letter Nov. 4, 1933 p. 1492) so supported my experience that I desire to add my own observations. I have not used such treatment in acute conditions.

In chronic painful articular conditions two recent cases have convinced me of the efficacy of local anesthesia in certain cases. I would feel hesitant in using it in unquestioned infection or in polyarthritis. But occasionally a case appears in which there are no definite demonstrable infective foci and drug therapy appears to be ineffectual. These persons are disabled, are never free from pain and have usually made the rounds of doctors and have had a session with the chiropractor.

H. M., a man aged 43 seen in bed for nearly one year after a fall on the ice had severe pain in and about the right hip joint. The pain was worse at night and was lancinating. His only relief was through occasional opiates. He was financially unable to have medical care. He walked only with effort and pain. One cubic centimeter of 1 per cent quinine and urea hydrochloride was given deep into the muscles about the right hip joint. Severe pain followed for about twelve hours followed by nearly complete relief. A second treatment was given four days later. The nocturnal pain ceased. He was able to walk and today four months later he has only a slight limp.

T. S., a man aged 40, a C. W. A. employee referred to me by the preceding patient had been troubled by a painful stiff right hip with darting pain down the back of the leg along the course of the sciatic nerve. This had continued for one year. He had taken some drugs but had been given many chiropractic adjustments with no relief. Physical examination showed definite infected (carious) teeth but otherwise nothing. He was advised to have the teeth cared for. In the meantime he was given 0.5 cc. of 2 per cent solution of procaine hydrochloride into the muscles about the right sciatic notch. Twenty-four hours later he reported relief. At intervals of three to five days he was given two more injections of 0.5 cc. of 1 per cent quinine and urea hydrochloride. After the second treatment he was able to dance. For a week diathermy treatments and massage were given and in the third week he was discharged free from all pain. At the end of two months he is still a grateful patient.

Naturally I know that statistics cannot be considered accurate when based on two cases but I believe that local anesthetics, administered with aseptic care in the region of a persistently painful joint should be given consideration.

A CASE OF EXTRA-OCULAR MUSCULAR PARESIS TREATED WITH GLYCINE

To the Editor—A man aged 32 first came to one of us (H. N. B.), Aug. 27, 1928 complaining of a recent diplopia. Paresis was present of all the muscles of the left eye supplied by the internal and external branches of the third cranial nerve. There was only a slight ptosis of the upper lid. The patient has been under systemic treatment ever since that time. He had an extremely sluggish patella reflex. Blood examination was negative. The Wassermann reaction of the blood and spinal fluid was negative. He was given several doses of neosarsphenamine and a mercury compound and potassium iodide internally. Examination of the paranasal sinuses gave negative results. He had some infected teeth, which were removed. The possibility

of multiple sclerosis was considered and a diagnosis was made by an English neurologist of myasthenia gravis, though there was a distinct inequality of the pupils.

The history of this case has been one of continued improvement and regression. The vertical diplopia, which worried him most, would improve and so would the ptosis. The extraocular muscles of the right eye would then become affected as the left eye had been.

On the patient's return from England last summer, he was placed on ephedrine at the suggestion of the neurologist in London, and there was some improvement noticed immediately. Then (after consultation with H. H. B.) glycine was given in the hope that we would obtain benefit from its administration in this unusual case. At the end of several weeks the condition improved so much that it was no longer necessary to cover one eye with an opaque lens, for the diplopia was no longer a source of discomfort to the patient. Since in this case there had been periods of improvement under the former treatment combined with rest, we were at first inclined not to be too sanguine, but the patient is firmly convinced that this period of improvement has lasted longer and that he has approached a more normal state than at any time since the beginning of the trouble. The patient is an extremely intelligent man and has given his condition a thorough analysis and expresses himself to be delighted with the improvement made.

IDIOSYNCRASY TO SALYRGAN

To the Editor—I have read with interest Dr. Carter Smith's report on the use of salyrgan in one patient over a period of three years (*THE JOURNAL*, February 17, p. 532). He states that only one instance of idiosyncrasy to salyrgan has been reported in the literature, that by Andrews in the *Lancet*, July 18, 1931. I wish to point out that Dr. Bongiorno and I reported a case of sudden death due to salyrgan in a nephrotic child, aged 4, in the *Canadian Medical Journal* (25:73 [July] 1931). The injection preceding the fatal one caused a chill fever, a morbilliform rash, anorexia and malaise. Good diuresis was obtained, whereas previous injections failed to provoke a satisfactory response. A week later the sixth and fatal dose was given, causing sudden death, which was anaphylactic in nature.

I. J. WOLF, M.D., Paterson, N. J.

THE RELATION OF THE USE OF ALCOHOL AND TOBACCO TO CORONARY OCCLUSION

To the Editor—In connection with the article of Drs. White and Sharber on the relation of alcohol and tobacco to angina pectoris (*THE JOURNAL*, March 3, p. 655) a brief report on the effect of these substances on coronary occlusion is, I think of interest.

Of 150 patients with coronary occlusion seen in private practice 52 per cent were total abstainers, 34 per cent occasionally used alcohol and 14 per cent were habitual drinkers. Of a group of 150 patients with the same age and sex ratios who did not have coronary occlusion 48.6 per cent were total abstainers, 40.6 per cent occasionally used alcohol and 10.6 per cent habitually used alcohol. There was therefore no apparent relation between the use of alcohol and coronary occlusion with the exception that one or two patients in the series developed occlusion during a period of exhaustion following a prolonged debauch. Of the same group of patients with coronary occlu-

sion, 34 per cent were nonsmokers, 36.6 per cent moderate smokers (not more than twenty cigarettes or three cigars or pipes a day) and 30 per cent were excessive smokers. Of the control group, 34 per cent were nonsmokers, 33.3 per cent moderate smokers and 32.6 per cent excessive smokers.

The number of cases analyzed is, of course, too small to warrant sweeping conclusions. Yet the figures suggest that, as in angina pectoris, so in coronary occlusion the use of alcohol and tobacco is of little if any significance.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

LEUKOCYTE COUNT IN APPENDICITIS

To the Editor—A patient having the symptoms and signs of acute appendicitis has the usual leukocytosis with more than 90 per cent polymorphonuclear leukocytes. Is there any danger in doing the operation with the polymorphonuclear count 90 per cent or above? One surgeon of my acquaintance will not operate on a patient showing 90 per cent or more. Is this good surgical judgment? What change occurs if any, in the blood count of the same patient as described when the appendix ruptures? Please give other signs of a ruptured appendix. Kindly omit name.

M. D. Oklahoma

ANSWER—A percentage of polymorphonuclear leukocytes in appendicitis of over 90 indicates pus or gangrene usually with a peritonitis. Occasionally there may be pus under tension. In general, the high percentage of polymorphonuclears indicates a severe infection or a massive toxic absorption, while a high total count indicates a high resistance. No matter how low the total count a high percentage of polymorphonuclears indicates a very severe toxemia.

Following perforation there may be a preliminary rise of the total count, but when toxic absorption becomes excessive there is a drop which may extend well below normal. However, the percentage of polymorphonuclears rises rapidly to over 90.

The differential count is the most important laboratory finding to differentiate between an improved and a more serious condition.

The general condition, including pulse rate, fever, blood pressure and local symptoms, will be the deciding factor in determining the diagnosis and the probability or length of time since perforation. Since the total count is usually high early after perforation with a high polymorphonuclear percentage, the presence of a falling total count or a rising percentage of polymorphonuclears is indicative of a progressive peritonitis and a grave prognosis.

The Schilling method of differential count is of value in prognosis since the increase of early or immature forms of neutrophilic leukocytes is of serious significance regardless of the total count.

With a perforation and spreading peritonitis, the outcome is usually fatal unless the peritonitis is localized to the region of the appendix or the source is removed in the first twenty-four hours.

In most cases the peritonitis remains localized and becomes walled off. Because of this fact, most physicians do not wish to operate with a peritonitis unless the patient is seen shortly after perforation. However, unless there is evidence of the peritonitis becoming walled off by localized symptoms or a mass it is quite likely that if the peritonitis continues to spread the patient will die unless a leaking perforated appendix is removed.

With a localized peritonitis as evidenced by a mass or very localized symptoms suggesting periappendicular abscess operation should be delayed. Most of these masses will subside and after two or three months the appendix should be removed.

If the toxemia increases with evidence of a local abscess, it should be drained preferably after a week's time. The drainage should be made without opening the general peritoneal cavity either through a muscle splitting incision or, in a pelvic abscess through the rectum.

A polymorphonuclear increase of over 90 is not a contra-indication to operate. It indicates the critical time for use of

the best surgical judgment as to the necessity for immediate operation, following a careful clinical examination. Only the immediate removal of a leaking perforated appendix with a spreading peritonitis can prevent a fatal outcome, while breaking up adhesions in a walled off peritonitis or perforated appendicitis should not be done by operation in the early stages.

ADMINISTRATION OF IRON—SODIUM CACODYLATE— COD LIVER OIL

To the Editor—Will you kindly send me information concerning the following questions? What are the relative merits of iron given orally and hypodermically? What is the relative quantity absorbed by the two methods? What is the value of sodium cacodylate injections as compared with an iron injection such as Ferrasse's (serpiginous ampoule)? Do you consider cod liver of tonic value for adults?

PAUL GRAY, M.D. Hightfield, N. J.

ANSWER—Hypodermic administration avoids local action on the alimentary tract but this can be avoided also by proper administration of suitable iron salts by mouth, e. g., insoluble preparations such as ferrous carbonate or poorly ionized iron compounds such as iron and ammonium citrate. When iron is injected all of it is absorbed, but most of it so rapidly eliminated (chiefly by the large intestine) that the amount which remains in the system is probably no larger than the quantity which remains when the iron is absorbed from the alimentary tract. Arsenic, whether administered in the form of cacodylate or otherwise, acts in a different manner from iron in that the former tends to increase the number of red blood corpuscles, the latter the amount of hemoglobin when administered in suitable doses. Cod liver oil is of tonic value only when there is a deficiency of vitamin A or D or of easily assimilable fat in the diet.

LUPUS ERYTHEMATOSUS AND SYPHILIS

To the Editor—Kindly inform me as to the prognosis and the latest treatment of lupus erythematosus in a young married woman who contracted syphilis about one and half years ago and who was under neosalvarsan and bismuth treatment for that length of time. Do you think there is a possibility of any relationship between the treatment of syphilis and the skin condition? If so is it advisable to continue with the antisyphilitic treatment? Please omit name.

M.D. New York

ANSWER—The prognosis in lupus erythematosus depends entirely on the type of the disease. It is poor in the acute disseminate variety with grave constitutional symptoms and fever. In the subacute disseminate variety the outlook is fair. In the ordinary chronic discoid type the prognosis is good although the course of the disease may be capricious and recurrences are not infrequent. The latest method of treatment is by intravenous injection of gold sodium thiosulphate, beginning cautiously with doses of from 5 to 10 mg. and reaching a maximum of from 50 to 100 mg. once weekly. Serious reactions have been reported from gold therapy, but in properly selected cases the results are excellent. When there is intolerance to gold, bismuth compounds may be tried intramuscularly. Local treatment will depend entirely on the severity of the inflammatory symptoms. At times, light freezing with carbon dioxide snow may be beneficial.

There is no relationship between the treatment for syphilis and the development of lupus erythematosus. Antisyphilitic treatment should be continued only if the serologic reaction is still positive or if clinical evidence of syphilis is still present.

POSTOPERATIVE GAS PAINS

To the Editor—What is the most recent theory as to the etiology of postoperative gas pains and what is the present concept as to the prevention and treatment? After a recent appendectomy the patient complained of gas pains for eight days in spite of enemata, rectal tubes and solution of pituitary. Some surgeons advocate castor oil on the second or third day after operation. Is this considered good practice? Please omit name and address.

M.D. Iowa

ANSWER—There is little after-effect on the movements of the gastro-intestinal tract due to etherization or section of the abdominal wall or exposure to the air with cooling.

The paralyzing effect on the bowel is less under local than under general anesthesia. Spinal anesthesia paralyzes the inhibitors and permits overactivity of the propulsive peristalsis.

The loss of propulsive peristalsis is constant after intestinal operations, while the rhythmic pendular movements may continue to function. A general reflex inhibition may be produced reflexly through the splanchnics by stimulation of the intestine or of any sensory surface at operation.

Following any intestinal operation a localized loss of motor function occurs, especially of the propulsive peristalsis, varying

with the extent of trauma to some extent. The pylorus may contract reflexly and delay evacuation as a protective mechanism to the intestine.

The distention of the intestine may to a large extent be prevented by maintaining tonus and the rhythmic contractions with morphine sulphate, although propulsive peristalsis may be but slightly affected. The protective action of morphine has recently been advocated in general peritonitis to prevent over distention with complete paralysis of the wall.

The recent use of a concentrated sodium chloride solution intravenously and as an enema has been highly satisfactory for postoperative distention. An enema of 150 cc. of a 10 per cent solution of sodium chloride gives better results than the usual treatment advocated for gas pains or distention.

Castor oil both before and after operation has been abandoned by most surgeons. Catharsis will tend to spread a localized peritonitis and is dangerous in appendicitis.

Large enemata may produce a similar bad effect and should be given for distention or gas pains only after that possibility has been considered.

Fecal impaction or colon spasm perhaps indicating operation may necessitate the flushing type of enema but rarely catharsis.

USE OF X-RAYS IN ACNE VULGARIS

To the Editor—I should like to have your experience in the use of x-ray tubes as a therapeutic agent in the treatment of acne vulgaris. Do you know where a technician could go to take a course in roentgen therapy? I will appreciate any information that you can give as to the advisability of the use of x-rays. J. T. GRAY, M.D. Stillwater, Okla.

ANSWER—Permanent cures can be obtained in selected cases of acne vulgaris to the extent of 87 per cent with roentgen treatment plus general medical attention. From eight to sixteen weekly treatments are usually required. It is the most certain way to obtain a permanent cure in three or four months. The treatment is not without danger and should be given only by a physician who is well trained in x-ray work and also who knows a great deal about acne vulgaris. Courses in roentgen therapy are given in many places. Courses in so-called superficial roentgen therapy are given at the New York Post Graduate Medical School. Courses may also be obtained at the Mayo Clinic, at the New York University and Bellevue Hospital Medical College and many other places. The indications and contraindications for the roentgen treatment of acne vulgaris are contained in chapter 28, page 431, of MacKee's book on X-rays and Radium in the Treatment of Diseases of the Skin, Philadelphia, Lea and Febiger, 1927.

DIFFERENTIAL DIAGNOSIS OF EDEMA

To the Editor—A woman aged 40 has an edematous condition involving the whole body. It does not pit on pressure. It is worse at certain times than at others. It is worse in the early morning but on exercise tends to disappear to some extent. The face seems to be more affected than other parts of the body. The heart and kidneys are normal. Allergy does not seem to play any part. What other conditions would you consider as an etiologic factor? Please omit name.

M.D. Arkansas

ANSWER—This question does not supply information relative to the duration of the condition and other physical signs apart from the edema. It must be remembered that any edema of long standing tends to lose its pitting characteristic.

A general, nonpitting edema without cardiovascular or renal disease would suggest the following conditions:

1. Myxedema, which occurs most commonly between 30 and 50 years of age and more commonly in women than in men. The puffiness occurs most noticeably about the face and eyes with characteristic swelling of the ankles and wrists. It is associated with a masklike expression, with mental and physical sluggishness, and with an extremely low basal metabolic rate. It may appear spontaneously or may follow thyroidectomy. The response to thyroid therapy is usually satisfactory.

2. Chronic hereditrophedema (Milroy's disease), which comes on early in life and usually affects only the lower extremities. In cases in which the upper part of the body has been involved the swelling has never been so great as that observed in the lower extremities.

3. Beriberi, a deficiency disease. Here the edema pits on pressure unless of long standing, and it is associated with other ailments, particularly a peripheral neuritis.

4. "Nutritional edema" thought to be due to a lack of protein in the diet together with an overabundance of fluid and salt. This edema usually pits on pressure and the dietetic errors should aid in the diagnosis.

From the information given, myxedema seems most likely.

ACETIC ACID IN RINGWORM

To the Editor—In Queries and Minor Notes in THE JOURNAL Dec 2 1933 I noticed Dr Rittenhouse's inquiry regarding a local application that would be effective in ringworm of hairy regions. The answering discussion mentions iodine and croton oil but does not name a simple remedy that I have found to be successful. Three dermatologic textbooks that I have examined also do not list this application.

Several years ago I noticed a barber making an application to a ringworm on a patron's face and inquired what he was using. The solution was 18 per cent acetic acid and the barber told me that one or two applications invariably cured the condition and that he also used it for barber's itch (sycois). Being quite sure that 18 per cent acetic acid would at least do no harm I began using this application for ringworm both on hairy regions and otherwise and have had constantly good results. Any tinea infection may be thus treated. I have used it in a few mild cases of epidermophytosis (athlete's foot) with benefit. The only objection is the burning caused by the application which is however of short duration. The application of acetic acid is not repeated sooner than three days. The ordinary ringworm subsides after one or two treatments. An infected ringworm of the scalp was treated six or even times before it became inactive. Usually ammoniated mercury ointment is prescribed to be used after the application of the acetic acid.

I do not know who may have originated this treatment of ringworm or whether it is in common use, but it has proved a satisfactory treatment of a common and usually stubborn condition.

A L NIELSON, M D, Harlan Iowa

ANSWER—Acetic acid has been used as a remedy for ringworm for a long time. Kaposi (Hautkrankheiten Vienna and Leipzig, Urban and Schwarzenberg, 1880, p 740) lists it as one of many remedies for ringworm of the scalp. H R Crocker (Diseases of the Skin, ed 2, Philadelphia, P Blakiston's Son & Co, 1893, p 865) recommends it for the treatment of tinea circinata, to be painted on the patch after it has been thoroughly cleansed with soap and water. Of modern writers O S Ormsby (Diseases of the Skin, ed 2, Philadelphia Lea & Febiger, 1921, p 892) mentions acetic acid as an adjuvant to other remedies, using it with or just before the other parasiticide. On the next page he lists glacial acetic acid as one of the strong remedies for ringworm of the scalp.

ANTIQUITY OF THE USE OF OPIUM

To the Editor—What preparation of the poppy was first used in the practice of medicine and when? What drug was used for the relief of pain during the first fifteen years of the eighteenth century?

C C HOWARD, M D, Glasgow Ky

ANSWER—Opium, the dried juice of the unripe poppy capsules, was no doubt known in remote antiquity, though infusions of poppy capsules and the pulp of unripe poppy seeds were probably used still earlier. The papyrus of Ebers (1552 B C) mentioned "spenn" seeds in the preparation of a "remedy to prevent the excessive crying of children." Hippocrates (460 B C) described the properties of the juice of the white poppy. Its employment at that time was chiefly in the form of highly complex mixtures such as the "mithridatum" of Damocrates or the theriaca of Andromachus. There can be no doubt that it was opium that was chiefly used for the relief of pain in the early part of the eighteenth century. In the later part of the seventeenth century, Thomas Sydenham had introduced its alcoholic tincture, made from opium and saffron with wine (Sydenham's laudanum), as the greatest of all remedies, and paregoric originated with Dr Le Mort, professor of chemistry at the University of Leyden between 1702 and 1718. It was also at this time that Dover, the inventor of Dover's powder, practiced a proprietary preparation known as "black drops," which was a vinegar of opium, was also extensively used at that time.

RINGWORM OF TOENAIL

To the Editor—One of my patients has a ringworm of both great toes following athlete's foot. This infection does not appear to affect the surface of the nail but has undermined the lateral edges for about one third of the nail's width. Please suggest treatment. Please omit name.

M D Michigan.

ANSWER—Ringworm of the nails is one of the most stubborn forms of fungous infection. Great patience and perseverance in treatment are required to cure it by nonsurgical methods but this is possible in most cases. Tincture of iodine best applied in the case described with a medicine dropper the solution being allowed to run under the nail, is one of the best remedies. After daily use for a time irritation is apt to occur when a soothing ointment as 10 per cent boric acid in petrolatum may be applied for a day or two, then Whitfield's ointment, 6 per cent salicylic acid and 12 per cent benzoic acid in ointment of rose water may be used daily for several weeks. Another course of the iodine solution should then be given. No preparation of mercury should be used while the effect of the iodine remains for

fear of a dermatitis. It is often necessary to change remedies several times before a cure can be achieved. Many other remedies are recommended, among the best of them an alcoholic solution of thymol, 1 per cent or stronger, or salicylic acid 10 per cent or corrosive mercuric chloride, 1:500, in alcohol.

One-fourth erythema dose of unfiltered x-rays, once a week for a maximum of eight weeks, or a stronger dosage of filtered x-rays if the nail plate alone is exposed, are sometimes successful when other measures fail. The rest of the finger should be protected by lead, and no irritating local application should be used for from two weeks before until two weeks after the treatment. After the effect of the rays has passed off, one or more of the remedies mentioned should be used for, if not wholly eradicated, the disease will recur.

Avulsion of the nail is seldom necessary but may be done if all else fails. It is best done under general anesthesia and followed by an iodine ointment, about 5 per cent, until the nail grows again, which requires about five months.

FINGER SUCKING BY CHILDREN

To the Editor—A boy, aged 4½ has nursed the two middle fingers of each hand chiefly the right since birth only when sleepy or asleep. He has developed normally in every way and had an attack of enteritis for four weeks when 13 months of age. Intervention to cure the habit was not begun early enough, and over the past year taping the fingers and splints to the elbows have been tried without success. The only local change noticed is a slightly loose condition of the two upper middle teeth. He exhibits a nervous tendency and recently has begun to bite his nails. I am in doubt as to whether to urge cure of the habit or recommend no treatment at all. Would the methods to use for such a cure tend to aggravate his nervousness? Your recommendation mentioning methods will be appreciated.

H QUILLIAN JONES M D Fort Myers Fla

ANSWER—Finger sucking or thumb sucking is of common occurrence in infancy and young childhood. As stated in the query, it is most likely to occur when the child is sleepy or asleep, or when he is nervous, fatigued or sick. The habit may persist from infancy into childhood. Most of these children recover from the habit spontaneously, though sometimes it continues for a considerable period.

The condition is sometimes difficult to treat, though if the child is manifestly nervous it is well to manage the general condition by rest, quiet, and the avoidance of overstimulation and fatigue. If too much is made of the condition, the habit may become worse and may continue in spite of attempts to forbid it, or by promises of reward or threats of punishment. The application of all tasting substances to the fingers gives only temporary results. A rubber nipple or pacifier may at times be used as a temporary substitute for the thumbs or fingers, though even this method usually fails. Globular aluminum mitts to cover the hands or thumbs prevent the introduction of the fingers into the mouth. In many cases the habit is stopped when the child grows older, and too strenuous treatment may tend to increase general nervousness and induce other bad habits.

ALOPECIA IN CHILDREN

To the Editor—Family history, Wassermann reaction and so on being negative what could one think of in a girl aged 4 years otherwise healthy with a growing depression over the right parietal bone and progressive clean baldness?

CLARENCE B FOSTER M D Greensboro, Va.

ANSWER—Alopecia may occur from one to six months after an acute fever. The hair begins to fall out, though this seldom leads to baldness. In mycosis fungoides, diabetes mellitus, myxedema or the cachexia of tuberculosis the hair may fall out and the condition may remain permanent. Alopecia is sometimes seen after the administration of thallium acetate or boric acid. It is observed after toxic doses of mercury, antipyrine or arsenphenamine. Congenital or acquired syphilis may cause alopecia.

In alopecia areata the hair is suddenly lost. The baldness occurs in sharply defined areas without signs of inflammation. The patches tend to spread peripherally. They are frequently multiple. Alopecia areata rarely occurs under 5 years of age. The affected scalp may be thinner than normal and the area is frequently depressed below the level of the surrounding skin.

Alopecia areata must be distinguished from ringworm although the former is rapid in onset and spreads diffusely and the bald areas are smooth and show no fungi, scales, vesicles or crust. In ringworm the fungus may be demonstrated and the extension of the bald area is slower.

Impetigo, erysipelas or other violent inflammatory diseases of the scalp may cause temporary bald areas, but the disease causing the loss of hair is readily observed.

PROPHYLACTIC VACCINATION AGAINST RABIES
IN DOGS

To the Editor—I have been unable to obtain satisfactory information as to whether the antirabies serum administered to dogs for the purpose of preventing rabies is considered effective in the prevention of this disease. Could you give me any information concerning this?

WILLIAM S. CRAWFORD, M.D., Tulsa, Okla.

ANSWER—There is no antirabies serum for the prevention of rabies. Prophylactic injection of dogs against rabies is done with so called vaccines of the fixed virus. There are two such vaccines available, namely, the phenol treated and the chloroform treated. In both these vaccines the virus is either dead or rendered so virulent that it does not produce rabies in rabbits on subdural injection. At present the experiments with the chloroform vaccine are encouraging, but no data are available as to its efficacy under field conditions (Schoenung H. W. Prophylactic Vaccination of Dogs Against Rabies *J. Am. Vet. Med. Ass.* 78:703 [May] 1931). The maximum duration of immunity after vaccination is thought to be one year.

CALCULATION OF LOSS OF VISION

To the Editor—I was interested in an article in a recent issue of *Hygiene* by James F. Lebensohn entitled "Mysteries of Vision." I have been puzzled several times to know the percentage loss of vision in compensation cases and would like to know more in detail the mathematics for the authors' calculations of various losses of vision. As I understand it the insurance companies consider a vision of 20/200 or less a total loss of vision as far as work is concerned. A vision of 20/30 is considered a 10 per cent loss of vision.

HOWARD I. MITCHELL, M.D., Lexington, Va.

ANSWER—On the basis of personal clinical investigations, A. C. Snell (*Ann. Otol. Rhinol. Laryng.* Oct. 31, 1925, p. 1367) found that total incapacity lay between a visual acuity of 20/200 and 20/300 determined by the nature of the employment, the age of the person, the duration of subnormal vision, and the will to work. Though most states have ruled that 20/200 is industrial blindness, mathematically this visual acuity represents a general visual efficiency of 20 per cent. Test charts can be procured from Bausch and Lomb, Rochester, N. Y., that alongside the distance notations have the A. M. A. ratings of visual efficiency. The full table with a consideration of the various factors involved in the determination of visual acuity has been presented by J. J. Lebensohn in the *Archives of Ophthalmology* 10:103 [July] 1933. For details of the method of calculation the article entitled "Percentage Evaluation of Visual Acuity" by A. C. Snell and S. Sterling (*Arch. Ophthalm.* 54:443 [Sept.] 1925), should be consulted.

ANTISTREPTOCOCCUS SERUM IN ERYSIPELAS

To the Editor—What is the present status of antistreptococcus serum in septicemia and in erysipelas?

MORRIS F. SUDLER, M.D., Lawrence, Kan.

ANSWER—The use of antistreptococcus serum in septicemia rests on an empirical basis. There is no evidence available to show that such treatment is specifically successful. The use of antistreptococcus serum in erysipelas is based on the demonstration that the streptococcus of erysipelas produces a specific toxin against which a specific antitoxin can be produced by immunization of horses with the toxin. In other words in the case of erysipelas there is available a specific antitoxic serum which, according to many reports, gives good results in early cases. However, not all reports of the results with the serum are favorable.

ELECTROCOUCTION WITHOUT MARKS ON SKIN

To the Editor—Is there sufficient experimental or clinical data to determine whether or not one can become electrocuted by coming in contact with electric light wires without having evidence of receiving burns on the skin?

ROSS TRIGG, M.D., Fort Worth, Texas

ANSWER—Current markings of the skin are not always present in cases of electrocution caused by currents of low tension (110 volts). Several cases have been reported in which most careful search failed to detect external evidences of electrocution (Meyner, K. *Wien klin. Wochenschr.* 35:619 [July] 1923; Furth *Munchen med. Wochenschr.* 64:926, 1917; Jellinek, S. *Wien klin. Wochenschr.* 36:157 [March 1] 1923; Spuren Kunde der Elektrizitat, Vienna, 1927). In some instances the current markings are easily overlooked, especially if they are located in regions of the body covered by hair or are on the hands of laborers with a thickened scaly skin. Examination with the aid of a hand lens may help to detect these insignifi-

cant changes. On the tips of the fingers, finger prints may help to locate the current marks, since in this region the normal linear markings are obscured.

TOXIN ANTITOXIN AND TOXOID

To the Editor—I noticed in *Queries and Minor Notes* in *The Journal*, Nov. 18, 1933, page 1663, an inquiry concerning immunity. I have had diphtheria four or five times. I received three courses of toxin antitoxin in different years. The Schick test is still positive but the reaction is less severe each time. I took two injections of toxoid and the Schick test was negative.

JOHN G. WILSON, M.D., Norristown, Pa.

ANSWER—The treatment of diphtheria with antitoxin tends to reduce the active immunity, so that it is quite possible for a person thus treated to have more than one attack of diphtheria. The prompt neutralization of the toxin by the antitoxin reduces the reactions of the body against the toxin. When the passive immunity due to the antitoxin subsides the person in question may become susceptible again to diphtheria toxin. The fact that the Schick test was positive after the injection of toxin antitoxin means that adequate active immunity had not been established at any time. On the other hand the two injections of toxoid appear to have established sufficient active immunity to make the Schick test negative.

PARENT'S BLOOD INJECTION AS PROPHYLACTIC
IN MEASLES

To the Editor—I please tell me whether an injection of blood from a parent who has had measles into a child will prevent measles. If so, what amount? Kindly omit name.

M.D. Georgia

ANSWER—Yes, the injection of such blood will prevent measles if it is injected in the incubation period. At least 4 or 5 cc. should be injected intramuscularly, and this quantity would better be doubled or quadrupled in older children and when the injection is made late in the incubation period.

SYPHILITIC PERIOSTITIS AND TABES

To the Editor—Kindly advise as to the treatment of syphilitic chronic periostitis of both legs as evidenced by x-rays. The blood Wassermann reaction is negative, the spinal Wassermann was not taken. Infection occurred twenty years ago and a few injections of neosalvarsan were given. There are severe night pains at intervals, varicose veins, marked wasting of the calf muscles and absent knee jerks. The pupils react sluggishly. The patient shows low blood pressure and loss of weight. Would such a case react to bismuth injections and iodides by mouth?

M.D. Pennsylvania

ANSWER—The absent knee jerk, sluggish pupils, nocturnal pains and wasting of the calf muscles suggest tabes or at least neurosyphilis. A spinal puncture should be done and a more complete neurologic examination. Chronic periostitis of the legs due to late syphilis should improve with injections of bismuth compounds and iodides by mouth. These should alternate with courses of mercurial injections and small doses of one of the arsenophenamines.

NO INCOMPATIBILITY IN MIXTURE OF CACODYLATE
SALICYLATE AND METHENAMINE

To the Editor—Would you please let me know what results when sodium salicylate is mixed with hexamethylenetetramine (methenamine) and also what is formed when sodium cacodylate, sodium salicylate and hexamethylenetetramine are all mixed together? Kindly omit name.

M.D. Alabama

ANSWER—Mixtures of these substances were made and solutions of these mixtures in water were prepared and both allowed to stand forty-eight hours. Neither the dry mixture nor the solutions showed the slightest evidence of change.

PSITTACOSIS

To the Editor—The question has come up as to possible hazards to public health in handling birds other than parrots and parakeets. I wonder whether you can tell me if any other species, particularly canary birds, are sometimes subject to psittacosis or any other disease which is transmitted to man.

M. J. LAKE, M.D., New York

ANSWER—The investigations of K. F. Meyer and his associates in San Francisco have shown conclusively that other birds than parrots and parakeets may suffer from psittacosis. Meyer and Eddie (Spontaneous Psittacosis Infections of the Canary and Butterfly Finch, *Proc. Soc. Exper. Biol. & Med.* 30:481 [Jun.] 1933) report the occurrence of psittacosis in a man and his wife who came in contact with canary birds having

the disease, to which they are highly susceptible. Canary birds may harbor paratyphoid-like organisms and consequently become a possible source of food poisoning. The birds also may harbor coccidial organisms in the respiratory tract which may be pathogenic for human beings.

APPENDICITIS WITH WORMS

To the Editor—Recently I examined an appendix that contained *Oxyuris vermicularis* in large numbers. How frequently does this parasite produce an appendiceal disturbance simulating an acute appendicitis? Please omit name. M D Illinois

ANSWER—Such observation is quite common, and it is agreed that the worms may cause appendicitis. They may produce appendiceal colic, they may irritate the mucosa sufficiently to cause catarrhal inflammation, and even hemorrhagic areas, and they may penetrate into the walls of the appendix, carrying infection with them. The frequency with which they actually produce symptoms simulating appendicitis is still quite as much *sub judice* as the more hotly debated question regarding the importance of fecaliths. It is, however, not great.

ACTION OF GLYCERIN HYPODERMICALLY

To the Editor—I request that you supply me with information on the action of chemically pure glycerin on the tissues if used hypodermically. What are its irritant qualities when used in this way in full strength or undiluted or in any dilution with water? It is understood of course that the preparation would be sterilized. H T CUMING M D Pace Miss

ANSWER—Glycerin is an irritant when injected in full strength or in any but great dilution. It also causes laking of the blood, owing, it is believed, to an osmotic effect on the red blood corpuscles during their passage through the area in which it has been deposited.

INSULIN IN DEMENTIA PRAECOX

To the Editor—Kindly give me the latest treatment of dementia praecox with insulin. A Viennese physician Dr Zuckel is supposed to have obtained superb results. I am interested as I have a relative who has dementia praecox. The treatment requires putting the patient into insulin shock. Could you give me detailed information regarding this treatment? M D, New York

ANSWER—We are not acquainted with the work of Dr Zuckel. His name does not appear anywhere in the last ten volumes of the *Quarterly Cumulative Index Medicus*, which lists all medical publications of any importance. Insulin is not mentioned as a remedy for dementia praecox in the comprehensive paper on endocrine treatment of the psychoses by Hoskins and Sleeper in the *American Journal of the Medical Sciences* (184:158 [Aug.] 1932). On the other hand insulin is frequently used in the treatment of all forms of psychosis with malnutrition due to unwillingness of the patient to take food.

HOLZKNECHT'S SPACE

To the Editor—What is Holzknacht's space with respect to the left lateral border of the heart on a roentgenogram? Kindly omit name. M D Pennsylvania

ANSWER—Holzknecht's space refers to the middle lung field in the roentgen screen or film image of the chest in oblique projection when the rays pass from the left posteriorly to the right anteriorly. In this projection there are three clear lung fields: the right, the left and the middle (Holzknecht's). This space is also referred to as the retrocardiac or the prevertebral space, bounded anteriorly and to the left by the posterior border of the heart, and to the right and posteriorly by the vertebral column.

CRIMSON ANILINE CRYSTALS OR ROSANILINE HYDROCHLORIDE

To the Editor—In *Queries and Minor Notes* in THE JOURNAL Oct 7 1933 page 1173 under Preparations of Cadavers for Dissection in Tropical Countries, you mention crimson aniline crystals for coloring the injection mass. I am unable to procure this chemical. It is not even mentioned in any of the books that are at my disposal here. Will you be kind enough to let me know another name or chemical formula under which it can be obtained possibly the source of its manufacture? Please omit name. M D Colorado

ANSWER—Crimson aniline, aniline red, basic fuchsin and magenta are trade names for the same thing, namely a preparation of rosaniline hydrochloride. The dye may be obtained from any of the dealers in dyes.

TRAUMA AND MYOCARDITIS

To the Editor—An obese man of 69 was struck by an automobile Sept 17 1933 and sustained some contusions and shock. He is bringing suit against an automobile insurance company to recover damages on the ground that the injury produced an acute exacerbation of a chronic myocarditis and permanent and total disability as a result. Is it at all likely that the previous heart condition could be made worse by the accident? Please omit name. M D Minnesota

ANSWER—The accident itself obviously could not have altered myocardial conditions. It does occasionally happen that pre-existing conditions are first called to the patient's attention after such an accident, when they are discovered by the attending physician. It is possible that the enforced rest and altered circulatory conditions might accentuate some condition already present but it does not seem possible that this could be more than temporary. It does not seem at all probable that permanent and total disability could result.

PROTECTION IN ROENTGENOGRAPHY

To the Editor—I am subjected to x rays in my work to the extent of half an hour of fluoroscopic work approximately five times a week. I should like an opinion if you feel that this might be sufficient to cause any feeling of fatigue or produce any secondary anemia. I do not use any lead gloves goggles or protective apron. Please omit name and address. M D Michigan

ANSWER—Half an hour of fluoroscopic work approximately five times a week may cause fatigue but not secondary anemia. It is imprudent not to use protective measures, such as apron and gloves.

OPERATIVE TREATMENT FOR SACROILIAC SPRAIN

To the Editor—What is the present status of the operative treatment for sacro iliac sprain? MERVIN T. SUDLER, M D Lawrence, Kan

ANSWER—The operative treatment of chronic recurring sacro-iliac pain is surgical fusion and is generally accepted. However, the surgeon should exclude such possibilities as arthritis of the lumbar spine, cord tumor and spondylolisthesis before resorting to this operation.

CHANCROIDS

To the Editor—In *Queries and Minor Notes* in THE JOURNAL January 20 page 231, Dr H B Taylor of Anking China asks for the latest and best treatment for chancroids. I have my own method, used since 1907 and I believe it is much better than any treatment you mention in your reply. It consists of ordinary cleansing and the application of one of the following solutions: (1) 25 per cent thymol iodine in ether; (2) 25 per cent iodoform in ether. Solution 2 is the stronger and more effective but the odor of the iodoform often precludes its use in society in which case I use solution 1 which is slower and not as good as solution 2. The ether vehicle is the successful keynote to its effectiveness as it carries the drugs quickly into the deeper tissues and ulcerated hidden recesses before the ether evaporates thus leaving the drug in direct concentrated contact all over the involved areas. The slight pain at the time of application lasts only a few seconds. It gives instant relief. As it quickly flows into all involved areas it is seldom necessary with its use to perform dorsal slits or circumcisions if syphilis is not also present. Both solutions are simple quick sure always available, cleansing soothing and easy of application and save many patients from the necessity of going to bed. They are also far superior to Merciere's solution even in buboes. The first day or two a few drops should be poured on the involved areas three or four times and as healing progresses and pain decreases the number of applications can be reduced to once or twice a day as indicated. The patient will soon tell of the relief obtained and will ask for it in preference to all other forms of treatment. I perfected these solutions while on duty on the Asiatic Station in 1907 and have used them ever since. Once tried all other methods of treatment for this painful and distressing disease will be discarded.

PAUL RANDOLPH STALNAKER M D, Houston, Texas
Captain Medical Corps U S Navy Retired

LIVER GROWN

To the Editor—In *Queries and Minor Notes* in THE JOURNAL Oct 28 1933 p 1414 there was an inquiry as to the term 'liver grown' as used in the Pennsylvania Dutch counties of Pennsylvania and in the issue of Feb 24 1934 a reply by Dr Yoder. The term as I have heard it used refers to enlarged abdomens particularly those that occur in rachitic children. A physician with whom I worked a number of years ago when rachitis was seen in more advanced stages than it is seen now and whose early years had been spent in the Dutch counties often referred to the pot bellied child as 'liver grown'. His explanation of the term was that no one among the natives realized the actual etiology of the condition but knowing that the liver was the largest abdominal organ believed that the pot belly was the result of liver enlargement. He further stated that individuals with abdominal neoplasms and at times dropsical persons were referred to in the same manner. In corroboration of his explanation I have since heard the natives of the Dutch counties refer to enlarged abdomens as 'liver grown'.

ARTHUR D. KURTZ M D Philadelphia

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILIGOLOGY. Written examinations will be held in various cities April 30. Oral Cleveland June 11-12. See Dr. C. Guy Lane, 110 Marlboro St. Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY. Oral (all candidates) Cleveland June 12. See Dr. Paul Titus, 1015 Highland Bldg. Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY. Cleveland June 11 and 12. Written July 11. Application must be filed at least 60 days prior to date of examination. See Dr. William H. Wilder, 122 S. Michigan Blvd. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY. Cleveland June 11. See Dr. W. I. Wherry, 1500 Medical Arts Bldg. Omaha.

ARIZONA. Basic Science. Little Rock May 7. See Mr. Louis I. Gelander, 701 Main St. Little Rock. Regular. Little Rock May 14-15. See Dr. A. S. Buchanan, Prescott. Homeopathic. Little Rock May 14-15. See Dr. A. S. Buchanan, Prescott. Eclectic. Little Rock May 14-15. See Dr. I. J. Marshall, 820 W. 11th St. Little Rock.

CALIFORNIA. Acupuncture. San Francisco May 16. See Dr. Charles H. Franklin, 470 State Office Bldg. Sacramento.

ILLINOIS. Chicago April 10-12. Subject of Reiss. Dept. of Reiss and Ed. Mr. Eugene R. Schwartz, Springfield.

MISSISSIPPI. Minneapolis April 17-19. See Dr. I. J. Embury, 150 St. Peter St. St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS. The examinations in Parts I and II will be held at centers in the United States where there are five or more candidates. May 7-9 (limited to a few centers) June 25-27 and Sept. 1-4. See Mr. Everett S. Howard, 225 S. 15th St. Philadelphia.

NEBRASKA. Basic Science. Omaha May 12. Application must be filed at least 15 days prior to date of examination. Dr. Bureau of Examining Boards, Mrs. Carl Perkins, State House, Lincoln.

NEVADA. Carson City May 7. See Dr. Edward I. Hamer, Carson City.

NEW MEXICO. Santa Fe April 2-10. See Dr. I. G. Cornish, Jr., 221 W. Central Ave. Albuquerque.

Missouri October Report

Dr. E. T. McGrath, state health commissioner, reports the written examination held in Kansas City Oct. 17-19, 1933. The examination covered 14 subjects and included 81 questions. An average of 75 per cent was required to pass. Seven candidates were examined, all of whom passed. Nine physicians were licensed by reciprocity and 2 by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Kansas School of Medicine	(1913)	85.2

Principles and Practice of Physical Therapy Edited by Harry E. Mook, BS MD DSc Chairman of the Editorial Board Associate Professor of Surgery Northwestern University Medical School, Ralph Pemberton MS MD FACP Professor of Medicine in the Graduate School of the University of Pennsylvania and John S. Coulter MD DTM FACS Assistant Professor of Physical Therapy at Northwestern University Medical School In three volumes. Fabrikoid. Price \$35.00 per set. Various pagination Hagerstown W. F. Prior Company Inc. 1934

It is significant that a topic which was on the borderland of scientific medicine in a previous generation should have advanced so greatly in the past twenty years as to require the development of a three-volume system for the presentation of the available data and the scientific considerations involved in its practice. A survey of the available books in this field indicates the need for a work of this type, since present-day physical therapy represents for the most part a combination of empiricisms of the past with the scientific dictums of the present. Because of the unsettled state of our knowledge in this field the American Medical Association established the Council on Physical Therapy. The present system, edited by three members of the Council, represents some of the order that has been brought into the field by the Council's work.

Volume I, entitled "Medicine," discusses physical therapy in various medical fields but is concerned also with such basic subjects as physiology of muscular action, posture, the history of physical therapy, the bases and the uses of exercise, heat and massage in medical conditions, the use of hyperpyrexia, and many similar topics. There are twenty-four chapters in the volume, all of them exhaustive, authoritative and practical.

The second volume is concerned more particularly with surgery. Here there are twenty-five chapters discussing fractures, traumatic injuries to the joints, nerve injuries, plastic surgery, obstetric paralysis, cancer of the skin, gynecologic conditions, and other topics.

The final volume, on the technic of physical therapy, is no doubt the volume most needed by general practitioners as well as by specialists and technicians in this field. It is essentially a book of directions. However, the instructions are supplemented in each instance by a statement as to the basis for the technic employed, the indications and the dangers.

The books are well printed in the form already tested as to its popularity by the systems of surgery and of medicine issued by the same publisher. The loose-leaf system offers an opportunity for keeping abreast of the times in a work in which progress is so rapid that only the loose-leaf system would seem to offer any guarantee against obsolescence at an early date.

Handbuch der Biochemie des Menschen und der Tiere Herausgegeben von Prof. Dr. phil. et med. Carl Oppenheimer. Ergänzungswerk. Band I (Ergänzung zu Band I III des Hauptwerkes). Halbband I Die Baustoffe der tierischen Substanz. Halbband II Biochemie der Zelle. Second Edition. Paper. Price 74 marks. Pp. 1154 with 40 illustrations. Jena. Gustav Fischer. 1933.

These supplements cover the literature up to 1932 in three parts: first, on building stones in animal tissues, second, on biochemistry of the cell and, third, on specific binding power and antibodies. These sections are subdivided on nearly the same basis as the original work. Several new subdivisions were necessary and several new contributors have been added or substituted. The first part is presented as follows: the inorganic constituents of the animal body, by Hans Aaron, Karl Klinke and K. Scharrer, four sections on simple nitrogen-free combinations up to five carbon compounds, carbohydrates and derivatives, benzene derivatives of nitrogen-free cyclic compounds, and amino sugars, by Heinz Ohle, two sections on the animal fats and waxes and the fatty acids and higher alcohols, by Egon Eichwald, carotinoids and vitamin A, by Paul Karrer, cyclohexane bile acids, sapotoxins, cantharidin and sex hormones, by A. Butenandt, sterols and vitamin D, by A. Lüttringhaus, two sections on amino acids and the structure and degradation of proteins, by Emil Abderhalden, three sections on acid amides, urea and guanidine, nitrogenous bases and pyrroles, imidazole and vitamin B, by F. A. Hoppe-Seivler, phosphatides and cerebroside, by E. Klink, sulphur-containing compounds, glutathione and insulin, by W. Dürschel, iodine-containing compounds, by Karl Junkmann, two sections on

pyrimidins, purines, nucleic acids and nucleases, by H. Steudel and O. Flössner, pigments containing pyrrole nuclei, by Hans Fischer and Karl Zeile, structure of high molecular weight combinations, by A. J. van der Wijk, polysaccharides, by Hans Pringsheim, general chemistry of proteins, by Hans Handovsky, two sections on special chemistry of proteins and degradation and derivatives of proteins, by E. Strauss and K. Burschikies, chromoproteins (respiratory pigments), by Felix Haurowitz, general treatment of animal enzymes and desmolases, by Carl Oppenheimer, esterases, phosphatases and sulphatases, by Eugen Bamann, carbohydrases, by Rudolf Weidenhagen, acylamidases, purinamidases and proteases, by W. Grossmann, arginase and histidase, by S. Edlbacher, aldehydases and alcoholhydrases, by C. Neuberg and E. Simon, dehydrases, by T. Thunberg, tyrosinases, by L. Pincussen, heavy metal containing animal oxidases, by Karl Zeile, nonenzymic intermediary catalyzers, by B. Kisch, animal toxins, by H. Schlossberger and F. Koch, and animal pigments of unknown nature, by O. Furth.

The second part includes three sections on Donnan equilibrium, surface tension phenomena and the colloidal state, by H. Handovsky, the biologic oxidation-reduction potential, by T. Thunberg, temperature control of living processes, by T. A. Maass, two sections on physical chemistry of enzymes and theory of the specificity of enzymes, by Karl Josephson, the mechanism of oxygen activation, by K. Zeile, mechanism of hydrogen activation, by Alfred Bertho, active iron, by O. Baudisch, two sections on energy exchange of living tissue and the general treatment of energy-liberating cell reactions, by C. Oppenheimer, descriptive chemistry of the cell, by S. Edlbacher, analytic studies on pigments, by A. Nagel, the exchange of cell constituents, by E. Gellhorn, three sections on autolysis, detoxification and influence of radiations on the cell, by L. Pincussen, three sections on the Pasteur-Meyerhoff reaction, synthesis and degradation of the phosphates and carbohydrate degradation in the animal cell, by K. Lohmann, the role of glutathione, by E. Bumm, three sections on general treatment of carbohydrate degradation, fermentation and endo-oxidation, by Carl Neuberg with Maria Kobel and Ernst Simon, insulin and tissue metabolism, by H. Blaschko, two sections on degradation of fatty acids and degradation of amino acids, by H. A. Krebs, and the degradation of nucleic acid, by H. Steudel and O. Flössner.

The third part presents two sections on antigens and antibodies, with especial reference to toxin action and antitoxic immunity and the general principles of chemotherapy, by H. Sachs, antitoxins and toxins, by H. Schlossberger and R. Krumeich, anaphylaxis and related phenomena, by Max Frankel, four sections on agglutination, antibodies against biocolloids, serodiagnostics of syphilis, and immunity against bacteria and protozoa, by Erich Putter, bacteriophages, by R. Otto, hemolysis, by Georg Blumenthal. The division adopted for the subject matter is such that considerable repetition is certain to result. It appears that in some cases this could have been avoided to advantage. On the whole, the reviews have been made quite international in scope. Undoubtedly certain subjects not included, such as vitamin E, pituitary hormones, cortical hormone, secretin, blood chemistry and essential amino acids, will be treated in the supplements to the other volumes of the original work. The reviews as presented are valuable indeed, as one might expect in view of the international reputation of many of the specialists chosen as contributors.

Diseases of the Nervous System By W. Russell Brain MA FRCP Assistant Physician to the London Hospital and the Royal London Ophthalmic Hospital. Cloth. Price \$8.75. Pp. 899 with 51 illustrations. London. Oxford University Press. 1933.

In a book of about 900 pages there is a discussion of the whole nervous system, including the neuroses. The book has an unusual feature in that there is a discussion of diseases of the nervous system in relation to life insurance. Necessarily the discussions are short, although some of the subjects are adequately covered while many are not. The book first discusses disorders of function in the light of anatomy and physiology. It is interesting in this connection that in a discussion on pyramidal syndromes the author follows the outline of Hughlings Jackson in discussing positive and negative symp-

Anleitung zur Vornahme von Leichenöffnungen Von Prof Dr R Maresch Vorstand und Priv Doz Dr H Chlari Assistent des Pathologisch anatomischen Institutes der Universität in Wien Cloth Price 3.20 marks Pp 144 with 17 illustrations Berlin & Vienna Urban & Schwarzenberg 1933

This is a memorial to Carl Rokitsky, who in 1834 became professor of pathologic anatomy in Vienna and contains an excellent photograph of him as the frontispiece. The authors are director and assistant, respectively, in the same institution. The technic of postmortem examinations which they describe is essentially that instituted by Rokitsky himself. The principle of this method is to conduct the examination so as to disturb the "physiologic" relations of the organs as little as possible and, as far as is feasible, to examine each organ in situ. This method has the advantage of doing the least amount of violence to one's esthetic sensibilities. The several chapters furnish detailed instructions for the proper examination of the external features of the body for opening the head and the investigation of its contents including the nose and its sinuses, the orbital cavity and the middle and internal ear, for removal of the spinal cord for examination of the organs in the thoracic and abdominal cavities, including Rokitsky's special technic for opening the heart, and for section of the extremities. A special chapter deals with the method of examining the bodies of the newly born, and another with the preparation of the body after the examination is completed. In an appendix the weights and sizes of the more important organs are tabulated according to age and sex. The authors begin their incision for opening the body at the larynx. There is no mention of the technic employed by most American pathologists of beginning the incision below the sternal notch with cross incisions below and parallel to the clavicles, or, in the case of female bodies, of beginning the longitudinal incision over the nuchoid process with a second connecting incision extending from axilla to axilla downward below the breasts. Nor is there any mention of the method of evisceration described by Le Count. But these newer methods would hardly be in place in a book which describes the technic that has been employed in one famous institution for a century. The authors' descriptions of the various procedures are clear. Many are illustrated by line drawings that are sketchy but adequate for their purpose. The volume is an excellent guide in the technic of postmortem examination but obviously cannot supply the experience necessary to the correct interpretation of the pathologic changes revealed. It emphasizes the desirability of complete necropsies properly performed.

Bentley and Driver's Text Book of Pharmaceutical Chemistry Revised by John Edmund Driver Ph.D. M.Sc. A.I.C. Lecturer on Chemistry in the University College of Nottingham Second edition Cloth Price \$7 Pp 538 with 41 illustrations New York & London Oxford University Press 1933

The first edition of this book was reviewed in *THE JOURNAL*, June 12, 1926, page 1858. The review pointed out that the volume took up substances described in the British Pharmacopoeia and was not based on the U. S. P. X. and so would be of little value in this country. The present volume appears to be carefully revised and a new section added but the criticism made in the review of the original volume is just as applicable to this book.

Weitere Beiträge zur Pathologie der traumatischen Gehirnblutungen Von O. Berner Pathologisches Laboratorium Lillerål Sykehus Oslo. Skrifter utgitt av Det Norske Videnskaps Akademi i Oslo. I. Mat. Naturv. Klasse 1933. No. 5. Udgitt for Oslo Kommunes Fond. Paper. Price 12.00 Kr. Pp. 106 with 88 illustrations Oslo Jacob Dybwad 1933

In this brief monograph the author presents the clinical and postmortem observations in forty-two cases in which death occurred subsequent to head injuries. The report is chiefly concerned with demonstrating that bleeding in the floor of the fourth ventricle and about the aqueduct of Sylvius occurs in such a high percentage of these cases as to be the rule. It is the author's opinion that such hemorrhages are the cause of death and he goes on to state that if such bleeding is absent death is in all probability due to some cause other than traumatic injury of the head. Any well considered contribution to the present inadequate knowledge of the pathology of head injuries is always welcome. There are however two major criticisms of this monograph that seem justifiable. This particular study might have advantageously been greatly condensed

especially the case reports, which constitute the major part, so that it would be suitable for publication in one of the current periodicals dealing with pathology or neurology. All readers familiar with the subject must entertain sincere doubts that such hemorrhage into the brain stem as the author describes is responsible for death in all cases in which death occurs as a direct result of cerebral trauma. It would seem from the author's presentation that this may readily be an important factor, but that it is the almost universal cause seems unlikely. The illustrations are for the most part satisfactory. There is no index, but in a work consisting almost entirely of case reports one is hardly necessary.

The Biology of the Protozoa By Gary N. Collins Ph.D. Sc.D. Professor of Protozoology, Columbia University Second edition Cloth Price \$7.50 Pp 607 with 225 illustrations Philadelphia Lea & Febiger 1933

The author has not attempted to give a complete account of the protozoa, which number about 15,000 but rather to tell the story of the biology of unicellular organisms with emphasis on such phenomena as cell division, maturity, sex differentiation and fertilization. Physicians will be especially interested in the chapter on parasitism and disease, which has been added in this edition, wherein are discussed the several hundred trypanosomes found in man and animals, the amebas, which have suddenly assumed unusual significance in the United States, and the sporozoa, of which the malaria parasite is an example. Besides a large bibliography at the end of the book there is a special bibliography at the end of each chapter. The illustrations, which are profuse, are mainly of free living forms.

Medicolegal

Medical Practice Acts—Electrical Treatments Administered by a Chiropractor—Mary Miller, a licensed chiropractor, and her assistant, Nancy Kehoe, were convicted of violating the medical practice act of New Jersey. They appealed to the Supreme Court of New Jersey. The evidence disclosed that Mrs. Miller had a sign, "Dr. Miller," on the window of her office and the words "Dr. Miller" on the door mat. She diagnosed the ailments of patients, prescribed a diet of food and soda as a medicine, and administered electrical treatments, which treatments were also given by Nancy Kehoe. In one instance at least Mrs. Miller directed the administration of opiates at the direction of a physician she called on the telephone. Mrs. Miller advertised herself as "Dr. Miller" under the classified list of physicians in the city directory. It is needless to say, said the Supreme Court of New Jersey, that such activities constitute the practice of medicine. The defendants contended, however, that because the act of 1920 (Pamphlet Laws, 1920 p. 15), which defined "chiropractic," was repealed, there was now no legal definition of the word, and inferentially that the scope of chiropractic practice was not limited. Even though the legislature has not since defined chiropractic, answered the Supreme Court, this fact does not deprive it of all meaning. The dictionary definition (Webster's New International) is "The practice of adjusting the joints, especially of the spine, by hand, for the curing of disease." The judgments of conviction were affirmed—*Miller v. New Jersey State Board of Medical Examiners (N. J.) 167 A 740* *Kehoe v. New Jersey State Board of Medical Examiners (N. J.) 167 A 740*

Malpractice—Hypodermic Needle Broken in Patient's Gum—The defendant, a dentist, inserted a hypodermic needle into the plaintiff's gum, to administer an anesthetic. The needle broke and about one inch of it remained in the tissues. Operations to remove the fragment were unsuccessful, and the embedded needle, according to the patient, caused her to suffer severe pain, headaches and nervousness. The patient and her husband sued the dentist and obtained judgment. The defendant thereupon appealed to the district court of appeals third district California.

Over objection by the defendant the trial court admitted testimony to prove an alleged conversation, in which the patient

her husband and the defendant participated and in which the defendant admitted he had made a mistake and promised to take up with his insurance carrier the matter of indemnity. Generally said the appellate court reference to the fact that a defendant is indemnified by a policy of insurance is prejudicial error, which cannot be cured by striking out the testimony or by an admonition to the jury to disregard it. This rule however does not prevent the introduction of evidence to prove a conversation such as was testified to in the present instance that contains an admission of responsibility along with reference to the existence of insurance. Because the evidence of this conversation was properly admitted there was no prejudicial error in referring to it in the argument to the jury.

The appellant dentist contended further that the trial court erred in permitting lay witnesses to testify concerning medical matters that properly could be testified to only by experts. The patient's husband was permitted over objection to testify that before the accident his wife was in good health physically and mentally. The lay evidence was properly admitted and the court citing 10 California Jurisprudence 978.

Under one of the exceptions to the federal ruling excluding the opinion of nonexperts the opinion of such a witness derived from observation may be received in connection with his statement of the facts of which it is based. It is said that this exception applies to questions of sickness and health.

The refusal of the trial court to instruct the jury that a licensed dentist is presumed to have the skill and learning and to exercise the judgment required by law and that this presumption can be refuted only by the testimony of expert witnesses was deemed proper, because the proposed instruction ignored the right of the jury to consider the testimony of lay witnesses on matters of common knowledge in determining the question of the defendant's negligence.

The judgment of the trial court in favor of the patient and her husband was affirmed—*Walker v. Luskland (Calif.) 24 P. (2d) 930*.

Medical Practice Acts Discretion of Board in Granting Licenses by Reciprocity—Walker was graduated by the St. Louis College of Physicians and Surgeons in June 1922 after a four years course of instruction. At any time between the date of his graduation and June 25, 1923, when the Missouri medical practice act was amended his professional qualifications would have entitled him to an examination by the Missouri State Board of Health with a view to his being licensed to practice medicine in the state. He understood, however, that he would not pass the Missouri examination and determined to apply to the Arkansas eclectic state medical board for a license to practice in Arkansas. To do so it was necessary for him to have been graduated by an eclectic medical school. In April 1923, he therefore enrolled in the Kansas City College of Medicine and Surgery. On October 12 of the same year he was granted a diploma and three days later, after an examination, he was duly licensed to practice in Arkansas. He practiced there for not less than a year.

Some time later he applied to the Missouri State Board of Health for a license to practice medicine in Missouri, to be issued by virtue of his Arkansas eclectic license, without examination. The state board of health in March, 1929, refused to grant him a license on that basis. He sought to compel it to do so by mandamus. The trial court refused to grant his petition and Walker appealed to the Supreme Court of Missouri, division No. 2. The Supreme Court found that the state board of health acted within its sound discretion in refusing a license. Persons licensed by reciprocity are granted a privilege not of right but of good will, and in the exercise of the board's sound discretion. Walker contended that the board rejected his application arbitrarily, unreasonably and capriciously, because in January, 1929, it had granted licenses without examination to four beneficiaries of the Arkansas eclectic state medical board. That fact, said the court, is evidence rather of an exercise of rational discrimination such as should mark the policy of the board in the observance of the comity declared by the statute. The applications of the Arkansas physicians who were licensed by the board showed that their experience and their recommendations by Missouri physicians differed from those of Walker. Walker's testimony warranted the inference that he

took the supplementary course in Kansas City only in order to be licensed in Arkansas and later to take advantage of the Missouri reciprocity statute. Reciprocity, said the court, does not countenance subterfuge.

The judgment of the trial court, denying the writ of mandamus was affirmed—*State ex rel Walker v. State Board of Health (Mo.), 61 S. W. (2d) 925*.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Treatment of Tuberculosis by Hyperpyrexia—Of the five patients suffering from tuberculosis who were treated by hyperpyrexia Duncan and his associates observed resolution over a period of from ten to eleven days in three sixteen days in one, and seventeen days in the other one. The usual rise of the patient's temperature was to 104 F or higher by mouth. The patients submitted to this treatment presented a poor

prognosis. The authors state that in those patients who show improvement the treatment should be continued with rest periods intervening and, when the patient's condition warrants, at higher temperatures for a longer time. They conclude that because of their patients' poor outlook at the beginning of treatment there is some definite value in hyperpyrexia as applied to pulmonary tuberculosis and that it is possible by hyperpyrexia to show roentgen and clinical improvement in pulmonary tuberculosis in a period as short as ten days.

Kahn Reaction in Aqueous Humor—Frahm presents the hypothesis that a positive Kahn reaction in the aqueous humor may be expected when the tissues from which that fluid is derived are syphilitic and that a negative reaction may be expected with a nonsyphilitic involvement of these tissues. He subjected forty-seven patients to puncture of the anterior chamber and determined the Kahn reactions in the aqueous humor, the blood and the spinal fluid. His observations substantiate the hypothesis. The most interesting exception to these observations can be expected in inadequately treated syphilitic patients showing iridocyclitis in whom the reaction of the aqueous may be positive and that of the blood and of the spinal fluid negative. From the cases investigated which showed involvement of the posterior part of the uvea or of the optic nerve the author could evolve no means of prediction as to the Kahn reaction in the aqueous humor. He observed no correlation between the Kahn reactions of the spinal fluid and those of the aqueous humor. He states that the Kahn test of the aqueous humor might be used as a differential diagnostic procedure in certain cases of uveitis of obscure etiology.

Use of Nupercaine in Ophthalmology—Bochner gives a summary of his experiences with nupercaine ophthalmology over a period of three years. On the basis of his results he concludes that nupercaine is a most satisfactory anesthetic for both instillation and infiltration anesthesia in ophthalmologic practice. The maximal strength should never exceed 1 per cent for instillation and 1,000 for infiltration. The maximal effect does not take place for at least ten minutes after the injection or instillation, and for operations involving traction on the iris an interval of half an hour should elapse between the instillation of the first drop and the operation, unless the instillation is supplemented by a retrobulbar injection. For instillation at least from 15 to 20 drops of epinephrine hydrochloride per ounce (30 cc) should be added to overcome the vasodilator effect. The epinephrine does not appear to increase the anesthetic action. There is only slight drying of the corneal epithelium, and no alteration in the tension or the influ-

ence on the pupal results. The action is much more prolonged than that of any other anesthetic and the drug is relatively less toxic. In more than 2000 cases no toxic reaction was observed when the drug was used in the strength mentioned. As a non-narcotic it lends itself readily to prescription in combination with other drugs, in the form of solutions or ointments.

Atypical Form of Paget's Disease Appearing as Generalized Osteosclerosis—Jaffe studied the bones from a man aged 55 which showed advanced osteosclerosis markedly intense in certain areas. The pelvis and spine minute bones, sternum and ribs were investigated. The long tubular bones could not be examined. Although Paget's disease was not plainly suggested in the gross except possibly in the ribs the microscopic studies led to the conclusion that the changes in the bones were those of Paget's disease. The histologic appearances were not similar to the typical mosaic arrangement of florid Paget's disease. The author concluded that the slow evolution of the pathologic changes was the reason for the absence of a mosaic arrangement such as appears in typically florid areas of Paget's disease. The slow progress of the disease permitted healing to keep almost abreast with its evolution. Furthermore the slow progress of the evolution of the disease and the concomitantly rapid healing led to the production of osteosclerosis rather than to the usual gross changes of Paget's disease. A somewhat similar case was described by Schmidt but was erroneously interpreted as osteosclerotic anemia. The relation of this condition to Pick's endosteal Paget's disease is not clear. Thus, Paget's disease may appear in atypical form the bones, in the gross, evidencing generalized osteosclerosis.

Leiomyosarcoma of the Duodenum—Andersen and Jaffe report a case of duodenal leiomyosarcoma with symptoms referable to repeated hemorrhage into the intestine for five years compression of the inferior vena cava for seven weeks and a palpable tumor in the right side of the abdomen for six weeks. The tumor compressed the inferior vena cava and thrombi were formed in the common iliac veins. Death resulted from pulmonary embolism. The authors analyze this case and the eighteen other cases of leiomyosarcoma of the small intestine that have been reported in the literature.

Roentgen Irradiation and the Healing of Wounds—Ritchie presents the results of an experimental investigation of the effect of roentgen rays on the healing of wounds with a brief review of the experimental and clinical literature on the subject. The early histologic features found in such irradiated wound tissue are (1) sluggishness of fibroblastic growth, (2) the presence of anomalous giant fibroblasts and (3) the persistence of a fibrin network for a varying period. The first of these is considered to be most important from a practical point of view and is most consistently seen when irradiation follows incision by approximately twenty-four hours. The second is the most constant characteristic, and, since it has been noted also in human tissues subjected to roentgen and radium treatment, the author thinks that its presence in inflammatory tissue is highly suggestive of a reaction to roentgen rays. It is obviously improper to carry the results of animal experimental work bodily and in detail over into clinical practice such an investigation can be seen in its true light only when thoroughly checked by clinical observation. Nevertheless enough evidence

has accumulated to warrant the statement that roentgen irradiation in doses ordinarily used for the treatment of malignant tumors administered within forty-eight hours after incision may definitely retard healing but has no bad effect as far as ultimate results are concerned.

Comparative Value of Tuberculinoprotein and Old Tuberculin—The results that Aronson and Nicholas obtained with small amounts of freshly diluted old tuberculin and tuberculinoprotein (MVA 100) show a close agreement but with larger amounts a larger percentage reacted to the old tuberculin than to tuberculinoprotein. When those who failed to react to old tuberculin and to tuberculinoprotein were retested approximately three months later a small proportion reacted to the old tuberculin but a larger proportion reacted to tuberculinoprotein. In a high percentage of those retested with tuberculinoprotein, evidence of sensitization was given by the appearance of the specific inflammatory reaction (Arthus phenomenon) at the site of injection.

Absorption of Insulin from Intestinal Tract—Campbell and Morgan demonstrated that once insulin gets into the portal circulation it is just as active as when given into the systemic circulation. This fact taken along with the observation that insulin is not rapidly destroyed in the intestine, indicates that the main reason for the failure of insulin to act when administered orally is that it is not absorbed from the intestine. The difficulty appears to lie in the selective absorptive power of the intestinal mucosa. The authors attempted to facilitate the absorption of insulin by combining it with lecithin. The compound formed is soluble in ether, is presumably of the nature of an adsorption compound, is active on subcutaneous injection, but is not absorbed from the alimentary canal either of the rabbit or of man.

Treatment of Intermittent Claudication and Thrombo-Angitis Obliterans with Parathyroid Extract—Conwell treated two patients having intermittent claudication and two having thrombo-angitis obliterans with parathyroid extract-Collip. The indications for its trial were no improvement with other forms of treatment employed previously and the presence of a hypocalcemia suggesting a metabolic disturbance with possible vasoconstrictor hyperirritability. Two of the patients were facing certain amputation. The parathyroid extract was given in amounts of 0.5 cc or 10 units subcutaneously every other day for ten injections. The improvement was relatively rapid and uniform. The attacks of intermittent claudication were controlled, permitting at least a temporary return to normal activity. The circulatory changes in the patients having thrombo-angitis obliterans were prompt and there was a complete control of the pain that had necessitated morphine. Return of warmth, moisture, diffuse reddish hue on elevation of the foot, loss of tenderness, improved sensation and motion of the toes, disappearance of the ecchymoses and deeper discoloration and there was a return of the pulse in the dorsalis pedis and the posterior tibial arteries. There were no untoward reactions. Calcium gluconate was given by mouth to two patients and not given to the other two but their responses appeared to be equal. The calcium of the blood plasma dropped slowly in one case.

- *Porphyrins in Human Disease V R Mason C Courville and E Ziskind Los Angeles—p 355

Porphyrins in Human Disease—Mason and his associates base their study on the clinical observations of four patients presenting the acute, idiopathic type of hematorporphyria, and also on the postmortem examination of the tissues of two of these patients who died from involvement of the nervous system with symptoms closely resembling acute ascending paralysis of the peripheral nerve type. They discuss the distribution and the chemical properties of the porphyrins and their relation to disease in human beings. No specific therapeutic measures have been found. Patients having the dermal type of the disease should be protected from the injurious rays of the sun and those having the acute toxic or acute idiopathic type of the disease must be treated symptomatically. Since the porphyrins form insoluble salts with calcium this element should be given in some form, although its therapeutic value is not yet known. The authors discuss the chemistry of porphyrins, the clinical features, symptomatology, pathologic anatomy, pathogenesis and so on as they pertain to porphyrins in the human being.

Use of Solution of Pituitary in Obstetrics—In discussing the use of solution of pituitary in obstetrics, Alden refers to the solution that contains 10 international units per cubic centimeter. In multiparas when slight contractions have been established 2 ounces (60 cc) of castor oil and 15 grains (1 Gm) of guinine bisulphate are given. Half an hour later 5 grains (0.3 Gm) of guinine bisulphate is given followed in half an hour by a hot soapsuds enema and in half an hour by the intramuscular injection of 2 minims (0.12 cc) of solution of pituitary which is repeated at half hourly intervals for six doses provided labor does not start in the meantime. The administration of solution of pituitary is stopped as soon as the patient is in labor. In primiparas the amount of solution of pituitary is reduced to 1 minim (0.06 cc). For uterine inertia during the first stage of labor solution of pituitary may be given in doses of 1 minim. Excessive use of solution of pituitary during the first stage of labor will result in tetanic contraction of the uterus and may rupture the body of the uterus the lower uterine segment or the cervix. A hot bath will often relieve the tetanic contraction or deep etherization may be instituted. During the second stage of labor solution of pituitary may be used in doses of from 0.5 to 1 cc. Repetition of the dose may

cause a distinct shutting down of the uterine musculature about the child. Once the placenta is expelled the routine intra-muscular injection of the full dose of 1 cc. of solution of pituitary is indicated, followed by, or coincident with, an injection of ergot. When bleeding is not controlled by one dose or when there is late relaxation of the uterus a 1 cc. dose of solution of pituitary may be repeated the possibility of a so-called pituitary reaction being kept in mind. In cesarean sections, solution of pituitary is of value in causing the uterus to shut down and in controlling bleeding after the extraction of the baby. Intramuscular or intravenous injection is employed chiefly. The intramuscular injection is made at the moment of incision into the uterus. If intravenous injection is used it should be decided on in the beginning and not given on top of one or two intramuscular injections. It should not be given before and not too long after the extraction of the baby. It may be diluted with from 5 to 10 cc. of physiologic solution of sodium chloride and should be given slowly. Solution of pituitary in conjunction with ergot is of value in cases of sub-involution of the puerperium when from 4 to 8 minims (0.25 to 0.5 cc.) is given three times a day. Solution of pituitary stimulates the unstriated muscle fibers of the intestine and bladder in atonic conditions. In postoperative distention following cesarean sections it may be administered every four hours in full doses. An intramuscular injection of solution of pituitary given half an hour previously will increase the efficiency of enemas in intestinal paresis. Retention of urine during the puerperium due to atony of the traumatized bladder is often favorably influenced by repeated injections of solution of pituitary intramuscularly three times a day. Solution of pituitary is contraindicated in cases of toxemia with high blood pressure, nephritis, myocarditis and arteriosclerosis.

Recurrent Vomiting—Recurrent vomiting, in childhood according to Kraus, is usually of a neuropathic origin and should be treated primarily by a study of the constitution of the child. Avoidance of physical and especially nervous fatigue is most important. Change in dietary habits with a reduction in the amount of pure carbohydrates and starches and with a relative increase in the amount of fats predisposes, in a certain type of child, to an accumulative, periodic toxemia characterized by persistent vomiting and prostration. It is most common in children from 2 to 7 years of age and is seldom seen after the age of 10. As the child grows older the mother becomes less insistent on the quantity of milk taken and more pure carbohydrates are allowed. This automatically corrects the tendency to recurrent toxemia, which these patients possess. Other predisposing causes are physical defects in the intestinal tract and chronic infection, especially in the tonsils. Attacks are precipitated by acute infections and by physical and mental exhaustion. Treatment of the metabolic imbalance by reduction of the fat and increase of the carbohydrates will clinically cure the majority of the cases. The acute attack, if severe, demands the liberal injection of fluids, preferably physiologic solution of sodium chloride or dextrose solution, until vomiting is controlled and diuresis is well established.

Scarlet Fever Immunization by Inunction—Ripps states that, of 112 Dick positive children completing treatment, fifty-seven were rendered negative from eighteen to nineteen weeks

after the last inunction. Cold cream inunction proved superior to hydrous wool fat in that it was quicker to absorb and produced a larger percentage of immunizations. The children who gave the most marked reactions to the Dick test were the most difficult to immunize. In children from 1 to 4 years of age the results were poor, only 33 per cent of the subjects in this group having been rendered negative. A higher percentage of immunization may perhaps be obtained with increasing dosage. As much as a 90,000 I.U. test dose of toxin has been given to a group without any reaction. Because of the ease of administration and lack of reaction, a continued study of this method of immunization should be made.

Treatment of Spastic Paraplegia by Repeated Cisternal Drainage—Clem performed repeated cisternal drainage in ten cases of spastic paraplegia. The infants have shown sufficient benefits to warrant a continuation of this type of treatment. Four were hopeless automatons and drainages were performed merely to relieve distressing symptoms. Of the remaining six, one child now 4 years of age walks runs and talks almost as well as other children of his age. When 22 months old he could not sit up, talk or recognize people or objects. His condition can be made much worse in a few days time by increasing his fluid intake from 10 to 25 or 30 cc. He becomes restless and nervous and he tires easily. He urinates larger quantities, he improves otherwise he remains listless and dull. Cerebrospinal fluid drainage and limitation of his fluids result in marked improvement within a few days. Improvement seems more rapid in the few cases in which treatment was begun at the age of from 15 to 24 months than in those of from 8 to 15 months. The author does not wish to leave the impression that this method of treatment is a cure for Little's disease but that it has greatly improved several children and relieved others of distressing symptoms.

 Modified Sabouraud Medium Suitable for Cultivation of Acid Fast Actinomycetes. Sara A. Scudder, New York—p. 116

Modified Sabouraud Medium for Cultivation of Acid Fast Actinomycetes—Scudder isolated an acid fast strain of actinomycetes from the blood in a case of acute mastoiditis complicated by sinus thrombosis, septicemia and arthritis by means of a modified formula of French proof agar. This strain was non acid fast on such mediums as the standard Bordet Gengou potato synthetic phosphate and Difco Sabouraud. The formula that the author employs consists of 4 per cent maltose, 1 per cent Difco peptone and 1.8 per cent flaked agar dissolved

in unfiltered beef heart or veal infusion instead of water. No adjustment in reaction is made. Glycerin and other carbohydrates may be added if desired. Slanted agar favors development of acid fastness in about four days. A grayish brown powdery substance develops on the upper portion of the slant simultaneously with the appearance of the acid-fast portions of growth. The acid-fast component appeared in young cultures (seventy-two hours) on this medium as branching non-acid fast mycelia containing acid-fast pleomorphic portions. Old cultures consisted of non acid-fast oval components and mycelia interspersed with acid fast oval components. The acid-fast characteristic was inhibited on all other mediums.

Treatment of Abscess of Bartholin's Gland—Dorough, in treating abscesses of the glands of Bartholin, exposes the gland by traction after the field of operation is made ready by the usual preparation and use of antiseptics and applies a drop of phenol to the mucous membrane just inside the mucocutaneous margin. As the area is tender, a few drops of a 1 per cent solution of procaine hydrochloride are injected into the tissue overlying the abscess by means of a fine hypodermic needle, entering through the anesthetized spot. This needle is then withdrawn and a large caliber one is inserted through the anesthetized area into the cavity of the abscess. With a syringe attached, the pus is withdrawn from the cavity and the amount removed is noted. By placing the gloved finger within the vaginal orifice and exerting gentle pressure, the operator is able to evacuate the cavity almost entirely. The syringe is detached and replaced by another syringe containing hexylresorcinol. The equivalent of one-half the amount of pus removed is injected into the cavity. This may be injected and then aspirated, washing out the cavity, but in all cases this amount is left in the cavity. The patient is then instructed to sit in hot water for a few minutes as soon as convenient and to repeat this each morning and night for two or three days. A preparation of foreign protein is then injected into the gluteal muscle. The next day the inflammation has markedly subsided and it may not be necessary to repeat the procedure. If the procedure is repeated it is rarely necessary to use any anesthetic for the insertion of the needle. As soon as tenderness subsides, the usual hot antiseptic douches are begun.

Clinical Recognition of Disease of Peripheral Vessels—Pickering believes that an essential step in understanding most disorders of the peripheral circulation is first to determine whether any structural lesion of the vessels is present. The author discusses the methods that he has found most serviceable in identifying structural disease of the vessels. In the absence of severe anemia, abnormal pallor of an extremity indicates emptiness of the minute vessels. Increased depth of color is due to a dilatation of the capillaries and venules of the skin as a result of injury. Postural changes in skin color are common in structural disease of the vessels but are by no means confined to these. Conspicuous pallor of the skin when a limb is raised and maintained for a few minutes above the level of the heart is strongly suggestive of a structural lesion of the vessels, and the height at which such pallor occurs is used by Buerger as an index of the degree of disease. The rate at which color returns to skin that has been blanched by pressure is frequently used as an index of the rate of the cutaneous blood flow. It is an unreliable test because the return of color is often from the surrounding venous plexuses rather than from arteries, and the rate of return then depends chiefly on the pressure in those plexuses. An important indication of the adequacy of the blood flow through a limb is the temperature of the surface of the limb, but skin temperature has wide fluctuations in health. The air temperature necessary to produce vasodilatation and warm extremities varies from subject to subject. Coldness of the extremities does not suffice for the diagnosis of arterial disease or arterial spasm. Of greater significance is an inequality of temperature between two symmetrical limbs similarly treated and exposed for the same length of time. Although it is the rule for a limb more affected by structural vascular disease to be persistently colder than its fellow the reverse is occasionally found. When the limb having the more affected vessels is the warmer, some other factor must be called to account for this. Pulsation may be retained in one or more of the main vessels of the foot or hand after the smaller arteries have become extensively diseased and the circulation to a limb may be almost normal in the absence of pulsation in its vessels, as is the case in the legs of patients with coarctation of the aorta. Allen has described a simple method for recognizing an organic obstruction of the ulnar or radial artery at, or distal to the wrist. In extremities that have been warmed by immersion in water at from 42 to 45 C (107.6 to 113 F) for ten minutes, it is usually possible in normal subjects to elicit capillary pulsation in the palmar surfaces of the hands and plantar surfaces of the feet by light pressure with a glass slide. The presence of capillary pulsation indicates that the arteries and arterioles supplying the corresponding area of skin are patent. The veins share in the general vascular relaxation produced by warmth, and the most satisfactory method of demonstrating the superficial venous plexus is to immerse the foot for ten minutes in water at from 35 to 40 C (95 to 104 F) and then to distend the veins by obstructing them in the leg with pneumatic pressure of from 60 to 70 mm of mercury.

Etiology of Blood Diseases Pathogenic Agent in Human Bone Marrow—The experiments of Friedemann and Eikeles demonstrated that in normal human bone marrow there is an agent which causes an encephalitis if injected intrathecally into rabbits. This agent cannot be one of the common bacteria, since all sterility tests have proved negative. The fact that the agent was present in all specimens of normal human bone marrow tested demonstrates that generally the agent is non-pathogenic for man, but this does not exclude the possibility that under some special conditions this agent may become pathogenic for man and cause disease. Their attempts to transmit the encephalitis from rabbit to rabbit through an indefinite series have had indifferent success.

Essential Hypertension—Although unwilling to accept the theory on which the treatment of Curya in cases of moderately high blood pressure was based, Gunewardene modified his method by substituting electrical stimulation of the skeletal muscles and submitting patients with high grades of pressure to treatment on these lines. As a preliminary, the patients were tested to see what effect the resulting muscular contractions had on the pulse rate, particularly as some of them were on the verge of cardiac failure. In every case the pulse rate dropped, sometimes by eight beats to the minute. The results indicate that in some cases of hyperpiesia the blood pressure drops to normal figures without rest or medicinal aid, there is also relief from distressing symptoms. In other cases there is relief from symptoms but pressures will not fall. These cases show impaired renal function as gauged by the urea concentration test. It is difficult to give an explanation of the mechanism by which the reduction of pressure is brought about.

Basophilia and Lead Excretion in Lead Poisoning—According to Bradham, lead poisoning is present when the first pathologic sign of the action of lead can be detected, and this is the presence of stippled red cells. Lead poisoning with disability is present when there is anemia in mild or severe degree, evidenced by a reduction of the red cells and hemoglobin and the presence of stippled red cells with or without symptoms of lead poisoning, such as malaise, constipation, joint pains and abdominal pains. If the patient is examined in the critical period for making a diagnosis of lead poisoning, that is, when lead anemia is present, punctate basophilia is always found, and this sign is practically specific for lead poisoning. Before making a diagnosis of lead poisoning, evidence of a lead intake should be sought, and this is to be found in a knowledge of industrial processes or in the amount of lead in the urine, or from the presence of a blue line.

 *My Method of Spinal Anesthesia with Nupercaine B. Quarella—p. 187
 Glandular Chelitis Precancerous State of the Lower Lip Touraine and Solente—p. 191

Spinal Anesthesia with Nupercaine—Quarella describes the technique that he uses for spinal anesthesia with nupercaine. Patients are prepared one hour before the operation by an injection of a freshly prepared ampule containing 0.0006 Gm of scopolamine hydrobromide, 0.015 Gm of morphine hydrochloride and 1 cc of a 10-100 aqueous solution of mannite. The dose may be adjusted depending on the age and condition of the individual patient. Fifteen minutes before the anesthesia the patient is given one or two ampules of ephedrine (each containing 0.05 Gm) subcutaneously, the dose depending on the blood pressure of the patient and the level of anesthesia to be obtained. The technique of anesthesia involves the following steps: drawing into the syringe of from 1.4 to 2 cc of a 1-200 solution of anesthetic, the amount depending on the general condition of the patient and the level of anesthesia to be obtained, spinal puncture of the patient in a sitting position and at a level between the twelfth thoracic and fifth lumbar vertebra, removal of from 5 to 10 cc of spinal fluid depending on the pressure and level of anesthesia to be attained, aspiration into the syringe containing the anesthetic of from 6 to 8 cc of spinal fluid, slow subarachnoid injection of the contents of the syringe, in cases of high spinal anesthesia, repetition of the aspiration of spinal fluid and reinjection, but with a lesser quantity, putting the patient quickly flat on the table with the head raised on a cushion in a more or less inclined position depending on the level of anesthesia to be reached, and waiting fifteen minutes at least, and twenty or twenty-five in cases of high anesthesia for the effect to be profound before starting the operation. The author believes that this technique compares favorably with other methods and other anesthetics. One of the special advantages of nupercaine rests in its short period of activity when introduced into the subarachnoid space, which limits its danger due to excessive diffusion.

 *Action of Hydrochloric Acid on Glycemia of Hepatic Patients A. M. Micheluzzi—p. 78
 Research on Chronaxia of Muscles and Peripheral Nerves in Cardiac Patients G. Borruo—p. 96

Action of Hydrochloric Acid on Glycemia of Hepatic Patients—Micheluzzi studied the effect of hydrochloric acid on the glycemic curves of patients presenting hepatic lesions. He made four separate glycemic curves, after administration of dextrose of dextrose and hydrochloric acid, of water and of hydrochloric acid alone. The dosages were 100 Gm of dextrose and 80 drops of the official solution of hydrochloric acid. The dextrose was dissolved in 200 cc of water and given to the patient on a fasting stomach. The hydrochloric acid was diluted in small quantities of water and given by mouth. The author found that the administration of hydrochloric acid causes a marked diminution in glycemia. This diminution is not uniform as to quantity but is always demonstrable and may attain high values. In one case there was a maximum rise of the glycemic curve to 63 mg per hundred cubic centimeters of blood, as compared to the curve obtained with dextrose only, while in another case the glycemic curve was lowered 70 mg. In all cases the lowering of the glycemic curve was more intense and more constant in the alimentary curves than in those obtained during fasting. In one patient the maximum glycemic diminution was 22 mg during fasting and after administration of hydrochloric acid and dextrose rose to 63 mg. The hypoglycemia due to hydrochloric acid may be explained by the synergistic action of internal and external secretion of the pancreas. The hydrochloric acid, which physiologically stimulates the pancreatic secretion may cause a formation of secretin, once it comes in contact with the duodenal wall, this in time may induce an excitation of the function of the pancreatic acini which may be followed by the passage into circulation of

a larger amount of insulin. The action of insulin, activating the enzymic secretion of the stomach and of the pancreas, the action of acid gastric juice on the pancreatic function and vice versa, and the belief that there exists in diabetic patients a gastric hypo-acidity and pancreatic hypofunction have convinced the author that the mechanics of direct stimulation of insulin secretion is the most probable explanation of the hypoglycemic action of hydrochloric acid.

Apicolysis Without Muscular Section—Pavlosky performs apicolysis and filling without muscular section by means of a vertical incision 8 cm long beginning at the level of the transverse apophysis of the eighth cervical vertebra and proceeding downward to the specified length. This incision is made midway between the spinal apophyses and the border of the scapula. The skin, subcutaneous cellular tissue and superficial fascia are incised and drawn sideways 3 or 4 cm. The aponeurosis is cut transversely and the muscle is separated following the direction of its fibers. The muscle is retracted, exposing the bundles of the rhomboideus, the fibers of which are separated in the center of the incision by the same maneuver used for the trapezius. The serratus minor posterior superior is then in view and its fibers appear in an oblique direction from above downward and from inside outward. The fibers are separated in the same direction and in the manner used for the other muscles. The three muscles (which cover the third and fourth ribs) are retracted. The resection of the third rib, the apicolysis and the filling are performed according to the usual technique. The muscular planes are reconstructed by approximating the muscles with small No. 00 catgut sutures. Perfect anatomic restitution is thus obtained. The operation is performed under local anesthesia by infiltration.

Emaciation—Von Bergmann considers the most important and most frequent form of emaciation a condition that has been referred to as 'hypophyseal emaciation'. He admits that the anterior lobe of the hypophysis may seem intact but points out that its internal secretion may be deficient, that there may be a pluriglandular disturbance and that the entire regulatory system may be impaired. He is convinced that the anterior hypophysis and the adjoining mesencephalic region are the most important factors in this form of emaciation. The patients lack appetite. Pain in the epigastric region and vomiting are often present, but the latter often yields to treatment with preparations of the anterior hypophysis. The pain in the epigastric region may lead to erroneous diagnoses and even to laparotomy. The basal metabolism is often reduced so that if the food intake should be normal obesity might be the result.

The intermediate metabolism is likewise subnormal. The administration of small amounts of insulin may produce severe hypoglycemic conditions. Forced feeding with insulin and dextrose is inadvisable, but dextrose alone may be given. The blood pressure is generally reduced. The majority of the author's patients were young women, in many of whom the menarche was belated. Psychic difficulties set in, lack of appetite led to emaciation and often menstruation ceased. He also observed that the temperature is frequently below normal and the pulse slow. Hair growth, particularly the axillary and the pubic is generally normal and there are no disturbances in the libido. Although there is a lack of appetite the patients often have an abnormal craving for sour and piquant foods, particularly raw cucumbers, tomatoes and sour fruits. The author thinks that such appetites may indicate a hunger for vitamin C. A sojourn in high altitudes may be helpful. The author considers endocrine preparations most effective particularly the extracts of the anterior hypophysis.

Treatment of Allergic Disturbances with Skin Extract—The preparation used by Kohler is an aqueous extract of the skin. The treatment was first suggested by Milbradt. It has a specific character and does not involve any danger. As indicated in a number of case reports, the author employed it successfully in bronchial asthma, hay fever and urticaria, but the treatment failed in a case of cold urticaria. The author administered by intravenous injection up to 10 cc daily. Later the doses may be decreased and the intervals prolonged. During the administration of the maximal doses attention should be given to focal reactions (increased allergic reaction to irritation). The treatment with skin extract is contraindicated in patients with exophthalmic goiter, because the maximal doses of skin extract increase the action of the thyroid. The treatment should be individualized carefully. The author admits that the material in which she tried this method is rather small, but she thinks that the favorable results justify further trials.

Spring Eosinophilia—It is pointed out by de Rudder that Moro ascribed the action of spring on the organism primarily to the increased sympathetic sensitivity. This heightened sensitivity of the sympathetic nervous system during spring seems more understandable in view of certain factors that play a part in the pathogenesis of rickets and tetany. The author calls attention to the lack of a certain portion of the ultraviolet rays, the Dorno rays, in the pathogenesis of rickets. In normal persons the sensitivity of the sympathetic nervous system can hardly be measured directly, but it seemed reasonable to investigate whether these changes in the irritability might perhaps be detectable in the number of eosinophils in the blood, since it is this type of cell that apparently has the closest relation to the sympathetic nervous system. The author studied the number of eosinophils in thirty-three normal persons. He found that the January values of from 0 to 2 per cent had advanced by March to from 2 to 4 per cent, and in the succeeding months, when the irritating action of spring had subsided again, the values decreased once more to those present during the winter. In experiments on guinea-pigs it could be shown that the spring eosinophilia is the result of the renewed exposure to the Dorno radiation after a prolonged existence in the absence of ultraviolet rays. The author thinks that the reappearance of the Dorno rays after their prolonged absence during the winter months probably play the most important part in the bioclima-

tology of sprang, for they produce an "irritation," to which even the healthy organism responds in various ways

Secretion of Gastric Juice and Localization of Zones of Hyperesthesia—Winkler calls attention to the observations of Heud, Mackenzie and others that visceral disorders produce hyperalgesia in the cutaneous areas that are innervated by the same segments as the diseased organ. Porges was able to observe in subacidity and anacidity, which he ascribes to gastritis of the body of the stomach, that the zone of hyperalgesia is on the left side, whereas in hyperacidity, which he ascribes to gastritis of the antrum, the sensitive points are on the right side. Since the localization of the hyperalgesic zones may have a certain diagnostic significance for the secretory action of the stomach, the author decided to compare the zones of hyperalgesia with the results of the examination of the gastric juice in a large number of patients with gastritis. He was able to corroborate the observations of Porges, for he found that reduced gastric secretion is accompanied by hyperesthesia on the left side and hypersecretion by hyperalgesia on the right side, in the region of the first thoracic segments. This indicates that in hyposecreta the body of the stomach (innervation from the left side) and in hyperacidity the antrum (innervation from the right side) is diseased. He thinks that exceptions to this rule are indicative of complicating disturbances in the region of the segments adjoining the zone of hyperesthesia.

Determination of Fructose in Blood—Stolir describes a simple titrimetric method for the determination of fructose for which 0.2 cc of blood or 2 cc of Folin-Wu filtrate is necessary. Fructose in contradistinction to dextrose, reduces the phosphorus-molybdic acid reagent, prepared according to Folin-Wu or Folin to a blue compound which in turn is titrated stainless in the cold with hundredth normal potassium permanganate. The test is made on the deproteinized blood filtrate, which is prepared either according to Folin-Wu or according to Hagedorn-Jensen in the modification of Stemitz and Riesen. The reduction of the phosphorus-molybdic acid reagent is proportional to the fructose concentration. The process is not strictly specific since diospyracetone methylglyoxal, glycerin aldehyde, ketol and acetol likewise have a reducing effect on phosphorus-molybdic acid. However, since these compounds do not occur in the blood under normal conditions, they do not interfere with the determination of fructose in experimental fructosemia. Dextrose produces only a minimal reduction, which in the computation is given consideration as the 'blind value'. The author gives the formulas of the equations that are used for the computation.

- Fracture of Head of Femur or Myositis Ossificans? H Engel and G Seefisch—p 168

Carbohydrate Metabolism in Hypertension, Acromegaly and Simmond's Disease—According to Kylin, sugar tolerance tests show that the blood sugar content increases more in diabetes without hypertension than in normal persons, whereas the increase in hypertension diabetes is about the same as in normal persons. Diabetes without hypertension reacts to insulin tolerance tests with a more pronounced reduction than is the case in diabetes with hypertension. A blood sugar increasing counter reaction develops much earlier in diabetes with than without hypertension. As two different hormonal actions regulate the blood sugar content, namely, a reducing factor (insulin action) and an increasing factor (action of anterior hypophysis and of suprarenals), it appears that in the diabetes with hypertension the counterinsular hormones exert the stronger influence. The demonstration of the counterinsular, prehypophyseal hormone (Lucke-Houssay, Evans) seems to make possible an explanation of the differences in

the reactions in diabetic patients with and without hypertension. The author assumes that the form of diabetes found in essential hypertension is generally caused by a prehypophyseal hyperfunction. He does not deny the possibility that in some cases of essential hypertension with diabetes the latter may be the result of arteriosclerotic processes in the pancreas. He calls attention to research that indicates the presence of a special type of diabetes in acromegaly, which is ascribed to overproduction of a blood pressure increasing hormone of the anterior hypophysis. In Simmond's disease, however, in which there exists an atrophy of the pituitary body, the blood sugar values are generally subnormal.

Kauffmann's Water Test for Determination of Cardiac Function—Bauke disagrees with Zimmermann's complete rejection of Kauffmann's water test (described in the *Medizinische Klinik* 29 1437 [Oct 20] 1933, and abstracted in THE JOURNAL, Dec 23, 1933, p 2088). The author shows that Heilbronner's modification of Kauffmann's original technic gives much more reliable results. Heilbronner administers the first 150 cc of fluid not at 7 a. m., but rather at 9 or even 10 a. m. However, even with the improved technic the outcome of the water test alone should never be considered sufficient evidence for a cardiac or circulatory insufficiency but should be considered so only in the presence of other clinical symptoms. The water test should be judged with the same caution and criticism as an electrocardiographic record, which alone would never be considered sufficient evidence of a cardiac lesion. The author recommends the combined use of electrocardiography and the Kauffmann-Heilbronner water test.

Monatsschrift f Geburtshilfe u Gynakologie, Berlin

- *Microscopic Observation of Blood Sedimentation (Kriele). Its Utilization in Prognosis and Differential Prognosis of Septic Infections of Genital Origin W Thierfeldt—p 204
- Differential Diagnosis of Narrow Pelvis I Kühbacher—p 216

Cerebral Pressure and Convulsions in Eclampsia—Spoljansky and Juzelevsky employed an especially constructed manometer to determine the pressure of the cerebrospinal fluid in patients with eclampsia and found it to be within normal limits. The normal pressure in the region of the cisterna magna is +150 mm of water if the person is lying down. If the person sits up, the pressure is negative. An increase in the lumbar pressure is not always accompanied by an increase in the cerebral pressure. Since nearly all the patients were under chloroform anesthesia while the pressure was tested, the authors determined the influence of chloroform anesthesia on the pressure of the cerebrospinal fluid and found that it effects no reduction in the pressure. Withdrawal of cerebrospinal fluid reduces the pressure in the subarachnoid space, no matter at what level the fluid is withdrawn. The authors conclude that their observations did not corroborate the theory that eclamptic convulsions are the result of increased intracranial pressure.

Microscopic Observation of Sedimentation—Thierfeldt der points out that the microscopic observation of sedimentation by means of Kriele's chamber gave hope that it would permit a reliable prognosis in septic infections. According to Kriele the prognosis is unfavorable (1) if the leukocytes show either conglomeration or increased adhesion or (2) if the thrombocytes show either conglomeration or are reduced to less than 120,000. The author shows that the behavior of the leukocytes in microscopic sedimentation cannot be utilized for the prognosis. With regard to the thrombocytes he agrees with Kriele in that he considers a reduction to less than 120,000 unfavorable, but he considers conglomeration a favorable sign rather than an unfavorable one as Kriele did. The author further discusses the differential diagnostic possibilities of the microscopic observation of sedimentation. He found that lymphogenic sepsis is readily differentiated with the method. In the eleven cases studied he always observed thrombocyte numbers of over 180,000 and in most instances of over 200,000. The leukocytes were diffused in the plasma column and never showed a pronounced conglomeration. Observations on six patients with thrombo-

phlebotic sepsis convinced the author that in this condition Kriele's method does not come up to expectations. For the early diagnosis of puerperal peritonitis, Kriele's method is important. In this condition the symptomatology is usually not clear in the beginning, and by the time the typical symptoms appear the process has advanced so far that surgical intervention comes too late to be of any value, but the author was able to corroborate Kriele's observation of thrombocytosis, the thrombocytes reaching values of over 400,000. However, he does not agree with Kriele on the sedimentation of the thrombocytes in puerperal peritonitis, for he often noted that the thrombocytes were more dense in the upper layers. There are three points that are important in order to obtain correct results: 1. The chamber must be exactly filled and no blood cells should escape over the rim. 2. The blood should not stand longer than two hours. 3. The blood should not be withdrawn during anesthesia, and pipets and syringes should never be cleaned with ether or alcohol. The correct estimation of the sedimentation picture requires a certain amount of experience.

Present Aspects of Influenza—From observations on influenza cases that occurred in Graz during 1933, Berger and his associates conclude that the clinical aspects of influenza today differ only quantitatively from those that were observed during the influenza pandemic of 1918, in that the symptoms are less severe. However, in the various smaller influenza epidemics that have occurred since 1918, the symptomatology has reached considerable degrees of severity more frequently than was the case after 1889-1890. As before 1918, the greater danger to the higher age groups has now again taken the place of the life threatening, hyperergic disease of the younger persons, which predominated in 1918. The hemorrhagic tendency and the involvement of the lungs, pleurae and sinuses are subject to regional differences during the same epidemic, but on the whole, they are now considerably milder than in 1918. The qualitative differences of the symptomatology (neuralgias, dyspepsias and so on) when compared to the pandemic are hardly greater than the regional differences within the same epidemic. The tendency to leukopenia increases proportionately to the degree of contagiousity. Rare forms of influenza, such as arterial thromboses, gastro-intestinal influenza or encephalitis, occur, provided there is a sufficiently large number of cases. Considering the symptomatology, there is not the least doubt that the disorder that occurred in greater and smaller epidemics since 1918 is the same disease entity as that of the pandemic of 1918.

Encephalitis and Influenza—De Crinis discusses the general nervous symptoms that begin or accompany an attack of influenza which, he thinks are largely manifestations of serous meningitic irritations. However if in the course of an influenza there develop manifestations that indicate disturbances in the cerebral parenchyma, the condition is designated influenzal encephalitis. The latter begins with general symptoms, occasionally with delirium or comatose conditions. According to the different locations of the foci monoplegia hemiplegia or aphasia may occur alone or in combination. The author points out that influenza may involve the peripheral nervous system in the form of a neuritis which may appear without signs of encephalitis being present and may develop during the acute phase of the disease as well as during the period of convalescence. The relations between influenza and epidemic encephalitis have not been completely explained as yet, but the author emphasizes that epidemic encephalitis differs from influ-

enzal encephalitis clinically, in its pathologic anatomic aspects and in its mode of dissemination. The treatment of influenzal encephalitis should be directed against the influenza. He recommends treatment with convalescent serum. Autohemotherapy in combination with antipyretics and with milk injections should be tried. Intravenous injections of methenamine have also been found helpful.

Treatment of Tuberculosis of Bones and Joints—Koppe treated nineteen cases of tuberculosis of the bones and joints with Klimmer's vaccine. In eleven cases he gained the impression that the vaccination produced a decisive turn in the course of the treatment. In six cases it was not certain whether the vaccinations exerted an influence, and two were not suitable for the estimation of the treatment, but not a single case was unfavorably influenced.

Klimmer's Vaccine in Prophylaxis of Tuberculosis—According to Hebel's experience, Klimmer's tuberculosis vaccine is harmless. Of forty-eight children whom he vaccinated forty-seven remained free from tuberculosis in spite of the fact that they were exposed to tuberculous infection. In four instances one each of the nonvaccinated parents developed tuberculosis while the vaccinated children remained free from the disease. Of three children who, as controls, were not vaccinated, one contracted tuberculosis of the bones, while the five siblings, who were exposed to the same extent but had been vaccinated, remained free from tuberculosis. The author realizes that the material is too small to arrive at a definite conclusion about the prophylactic value of the vaccine, and he thinks that the specific immunization should never be the ground for the neglect and omission of the methods that have proved their worth such as isolation of the patients, whenever it is possible, correct treatment of the sputum and improvement of the general condition by better nourishment. However, a specific remedy is nevertheless desirable, provided it is harmless.

Extraperitoneal Cesarean Section—In the last five years, 308 extraperitoneal and 160 intraperitoneal cesarean operations were performed at Kaboth's clinic. He gives a detailed description of the procedure that he follows in the extraperitoneal method. In opening the abdominal wall, the attainment of a secure cicatrization should be kept in mind. The cutaneous incision and the division of the fascia are in the longitudinal direction but the cutaneous incision is higher up toward the umbilicus, while the fascial section is made lower down toward the symphysis. The author describes the exposure of the neck of the uterus in an area large enough to permit the passage of the head. The lower pole of the peritoneal sac must be pushed upward and the bladder toward the side. Because of the frequent deversion of the uterus, the entire intervention is best made to the left of the median line so that the bladder can be shifted toward the right. The cervical incision, delivery and uterine suture are the same as in case of the intraperitoneal procedure. Following completion of the uterine suture and after the removal of the blood clots, the peritoneal sac and the bladder fall into place. Drainage of the pre-cervical space should be done through a special opening. A dressing forceps is pushed forward from the inside and where it reaches the abdominal wall an incision is made (2 cm) and a strip of gauze is introduced into the pre-cervical space. The drainage

opening is at the external rim of the abdominal rectus. Thus the abdominal incision proper is not used for the drainage. In discussing the results of the extraperitoneal method the author emphasizes that the maternal mortality was smaller than in the intraperitoneal method in spite of the fact that the material in which the extraperitoneal procedure was followed had more unfavorable cases. He considers the extraperitoneal method the least trying for the mother and he recommends it for all cases in which delivery by abdominal section is necessary.

Etiology of Cervicovaginal Liquefactive Fistulas.—Welsch relates two clinical histories that illustrate how cervicovaginal liquefactive fistulas may be caused by the introduction of laminaria bougies. In one case the laminaria were introduced for the purpose of completing an abortion. They slipped into the uterus and because of an anteversion their external ends pressed against the posterior cervical wall. A pressure necrosis developed, rectal tenesmus set in and led to severe straining and finally the posterior cervical wall was perforated and the bougies protruded into the posterior vaginal vault. A cervicovaginal liquefactive fistula would have developed but the bridge between the perforation and the external uterine os was divided immediately after the uterus had been evacuated. The second patient was a woman in whom laminaria bougies were introduced for the treatment of dysmenorrhea. The fistula was not discovered until four years later when she asked advice because of sterility. The author cites three other cases from the literature in which laminaria bougies caused liquefactive fistulas in the cervix. He advises against the ambulatory use of laminaria bougies.

 Material for Study of Aphasia. M. E. Sobol —p. 45

Acute Febrile Syphilis of Brain.—Popov and Aronovich report six cases of acute febrile syphilis of the brain. They believe that it deserves consideration as a special form of neurosyphilis. The disease is characterized by an acute or subacute onset followed by exacerbation of symptoms. The symptoms in the beginning are grave but the response to antisyphilitic treatment is prompt. The development of the disease is not dependent on the duration of the syphilitic infection. It occurs predominantly within the first few years and even months of the syphilitic infection. Clinically two types may be distinguished: the purely meningeal and the meningo-encephalitic. The specific etiology is recognized from the history and the presence of humoral reactions in the blood and the cerebrospinal fluid. The Wassermann reaction was sharply positive in their cases. The pleocytosis of the cerebrospinal fluid may be pronounced, with a predominance of polymorphonuclear neutrophils. The histopathologic picture is one of meningo-encephalitis with a predominance of meningeal alterations. The entire process may be regarded as a flare up of a chronic meningeal syphilis.

Tuberculous Meningitis of Adults.—Rosenboym reports twenty-two cases of tuberculous meningitis of adults verified at necropsy. He concludes that tuberculous meningitis may occur at any age. The incidence of the disease was most pronounced in February and in May. The peculiarity of the tuberculous meningitis of the adults consists in the prominence of the symptoms of headache and vomiting. Other signs of meningeal irritation, particularly that of Kernig, are less pronounced. In adults, tuberculous meningitis is more frequently associated (68 per cent of the author's material) with general miliary tuberculosis. The isolated form was seen in 22 per cent of the cases. The author has not seen an isolated form in children. Tuberculous meningitis both in adults and in children is a secondary disease. The primary focus in childhood is seen most frequently in the lymph nodes while in adults it may be found in the various organs, but most frequently in the lungs. The spread of infection in adults takes place most probably by the hematogenous route.

 *Microsedimentation Reaction with Landau's Pipet. S. Frostad —p. 170
 Case of Hypochloremia with Azotemia. O. I. Olsen —p. 178

Cautey of Endopleural Adhesions.—Tuxen says that endopleural adhesions are present in three fourths of all cases of pneumothorax. Moderately extensive adhesions or adhesions over the stronger part of the lung may offer so slight an obstacle to collapse that the pneumothorax does become effective with extensive unfavorably situated adhesions, a partial pneumothorax results. Thoracocauterization is indicated on clinical roentgenologic signs of ineffective pneumothorax, and even in clinically effective pneumothorax roentgenologic adhesions over the cauter or preventing selective collapse constitute a strong indication for cauterization. With intended or performed bilateral pneumothorax, cauterization of every fairly easily divided adhesion is called for. Roentgen examination does not give exact information as to location, extent or character of the adhesions and the feasibility of thoracocauterization must be determined by thoracoscopy. Thinner threads and strands and membranes at a good distance from the lung are easily operated on; thick pedicles, membranes close to the lung, hour-glass adhesions and thin finger-like pedicles with short or no fibrous transition to the chest wall are difficult to operate on. Difficult adhesions are divided only on strict clinical roentgenologic indication. If the grave finger-like pedicles cannot be divided pneumothorax should be discontinued and thoracoplasty done instead. Flat adhesions cannot be operated on. The time of operation should not be earlier than two months after pneumothorax, with too long delay, exudation may render the procedure more difficult. Long, thin, solitary threads should be divided early. In ninety-two cases of thoracoscopy in Tuxen's material, follow-up information was available. In the seventy-nine cases of ineffective pneumothorax thoracocauterization was done, with complete success in forty-two and improvement in twelve and in the thirteen cases of effective pneumothorax thoracocauterization was successful in twelve with adhesion-free collapse in one and considerable loosening in nine. All types of adhesions were seen. The worst complication, spontaneous pneumothorax due to rupture of the lung occurred in five, two being fatal. These five together with four illustrating the value and the limitation of the method and one of unusually grave lung pedicle, are described.

Hemolysis in Pregnancy and Abortion.—Hartzitz thinks that in his case with abortion before admission there had been a tendency to hemolysis probably due to the pregnancy and the quinine taken by the patient to induce abortion had increased the hemolysis, which developed into a pure hemoglobinemia and hemoglobinuria, methemoglobinemia and methemoglobinuria finally causing a fatal uremia. The acute glaucoma with which the disturbance set in and which passed into a panophthalmia is regarded as secondary and ascribed either to increased secretion and changes in the aqueous humor or to action of the quinine directly on the blood vessels. Microscopically, brown and reddish brown masses were seen almost to block the renal canals, there was no glomerulonephritis and but little degeneration of the renal epithelium.

Asymmetrical Sacralization of Fifth Lumbar Vertebra.—Ingebrigtsen sees in his third case of operative asymmetrical sacralization with recovery here reported, added support for the conception of this disorder as a clinical entity, because the anatomically established sacralization is really the cause of the pain syndrome.

Microsedimentation Reaction with Landau's Pipet.—Frostad says that he found the results of microsedimentation to be as reliable as those of Westergren's sedimentation reaction while the apparatus and the technic are simpler. The method has many advantages when venipuncture is difficult especially in pediatrics.

PULMONARY TUBERCULOSIS

RECENT TYPES OF OPERATION

HOWARD LILIENTHAL, MD

NEW YORK

Tuberculosis is a disease that begins locally and is followed by general dissemination. In this respect it resembles many other infectious diseases as, for example, syphilis, and, like syphilis, it destroys tissue, leaving scars or fibrosis when the infection has been overcome. The local destruction by either tuberculosis or syphilis may produce mechanical conditions that are permanent even though the disease itself is no longer active. One example is stricture of a hollow viscus. These residual disturbances may require operations for relief or even to save life.

Since the discovery of reliable methods of killing the spirochete, the need for operations in syphilitic disease is seldom felt. On the contrary, deformities left by tuberculosis of the lungs are still frequently encountered and form the principal group that calls for operative therapy. The cure of tuberculous cavities with their dangers of locally spreading the infection, of septic absorption or of mixed bacterial contamination and of further destruction of pulmonary tissue is the chief object of operative procedure.

I feel that the day must come when a direct biologic attack on the bacillus of tuberculosis will result in the control and, perhaps, in the final disappearance of the disease, but at present one can hope only for an arrest of progress with cicatrization with or without calcification or ossification, which in ordinary circumstances prevents the continued advance of the malady.

Dr. William Charles White¹ recently delivered an absorbingly interesting lecture at the New York Academy of Medicine. It is an index of what is going on in the investigation of the biologic aspect of the disease. Every physician should read this paper. In the very first paragraph the modern concept of tuberculosis is made so clear that it raises the fire of prophecy in the reader's mind.²

Methods employed in the treatment of this disease may be divided into three main groups:

- A. Medical treatment so called which might better be described as the nonoperative treatment by hygiene.
- B. Operative treatment.

Both of these have for their object the resulting "cure" by rest and by scar formation of the least harmful character.

The third method, which is now under intensive investigation, is

C. Biologic treatment

Since this paper will deal solely with operations most of them comparatively new, I will not discuss the medical treatment including hygiene, voluntary rest, and the like, nor will I touch on the biologic therapy of the future.

I will also not report on the work of predecessors from which the therapy of today has arisen. So quotations from Hippocrates will not be given nor even from Carson³ (all credit to him and his 1822 prophetic suggestions).

Surgery in this paper is intended to signify treatment by mechanical means with or without a cutting operation.

I assume that the reader has a good working idea of what surgery is supposed to accomplish in pulmonary tuberculosis, so I will merely enumerate its four main divisions, which may be practiced singly or in combination:

1. Extrathoracic procedures.
2. Operations on the thoracic wall.
3. Transpleural operations not on the lung.
4. Attacks on the lung itself.

EXTRATHORACIC PROCEDURES

Of the extrathoracic procedures, the most common is that of paralyzing the diaphragm on either one side or both sides by interrupting its nerve supply.

There has been some question concerning the inhibition of the act of expectoration because of the phrenic paralysis. I have not found this to be the case but rather the opposite, since the paralyzed diaphragm in coughing is pushed violently upward by the compressed abdominal viscera. Burrell⁴ takes the opposite view and states that "phrenic avulsion and thoracoplasty are contraindicated" in tuberculous abscesses with much expectoration. It is almost needless to say that Burrell's conclusions will not be upheld by most observers.

Paralysis of the diaphragm, by attacking the phrenic nerve, may be brought about by (1) contusion, (2) injection,⁵ (3) division, (4) resection and (5) avulsion.

³ Caron, James. Essays. Physiological and Practical. Liverpool. F. B. Wright. 1822.

⁴ Burrell, L. S. T. Lancet 1: 356 (Feb. 18) 1933.

⁵ A. Rodet (Paris med 30: 100 [July 29] 1933) abstr. J. A. M. A. 101: 1115 [Sept. 30] 1933) describes an injection made by inserting a needle 5 cc below the base of the xiphoid process and 5 mm to the side of the median line and directing it obliquely upward so that it reaches the insertions of the diaphragm behind the cartilage of the seventh and eighth ribs. There is characteristic neck and shoulder pain after the injection which indicates that a phrenic nerve has been reached. This method seems unnecessarily complicated and perhaps even dangerous.

Read before the First District Branch of the Medical Society of the State of New York, Graslands, Oct. 11, 1933.

¹ White, W. C. Bull. New York Acad. Med. 9: 433 (July) 1933.

² The tuberculous process involves the living together of two independent organisms: the tubercle bacillus and the monocyte amebic cell.

If the temporary effects of the contusion of the phrenic nerve by crushing with forceps wears off too quickly, Douglass⁶ states that a second contusion may be performed with little difficulty through the scar of the former incision. He has also affirmed⁷ that phrenic neurectomy can be regarded as successful only "when the x-ray film no longer reveals a cavity and when the sputum has been negative on concentration for at least three successive months." This definition of the success of phrenicectomy seems rather rigid when one con-

siders that tubercle bacilli in the sputum may come from a lesion, perhaps a very small one, in the opposite lung.

In general, the sole method by which the permanent arrest of the disease can be demonstrated is by roentgenograms. I agree with Miles⁹ that if after six months of roentgenologic observation there is no vis-

Fig. 1 (Matthew S.)—Transverse position of stomach with kinking of pylorus as a result of right phrenic neurectomy.

ible activity or change, the disease may be regarded as stationary or arrested.

In considering these valuable procedures on the phrenic nerve, much has been said regarding their harmlessness and perhaps too little concerning untoward effects that are occasionally though rarely observed. Truesdale⁸ of Fall River referred to the effects of gastric dysfunction by dislocation of the stomach. This had usually been noted after left-sided operations, but recently disturbances on the right side have also been observed.¹⁰ In one of my own cases in which posterior symplectomy had been preceded for some months by phrenic neurectomy, the patient had serious abdominal symptoms with vomiting which necessitated attempts at gastric lavage. Four surgeons and one gastrologist attempted to pass the stomach tube, in every case without success. The tube entered the stomach cavity only once and was instantly expelled. All other attempts were futile both with the ordinary stomach tube and with the intranasal Levine tube. Later on when the patient was convalescent (without lavage) a roentgen examination of the esophagus and stomach revealed no abnormality of the former but a transverse position of the stomach and with the rising of the right diaphragm, apparently an angulation of the pyloric region, which probably accounted for the acute dilatation with vomiting, regurgitation and belching (fig. 1).¹¹

Phrenic nerve avulsion is the most radical method and on the whole is the most generally applicable. The approach that is oftenest employed is through a transverse incision about an inch or more above the clavicle, where the nerve, when normally situated, can be easily

found as it passes downward and inward across the anterior scalene muscle. The exposure which I employ has the advantage that the resulting scar is almost invisible and that identification of the nerve is easy.¹² Dr. H. Ryerson Decker of Pittsburgh has stated that he employs the method as a routine.¹³ The incision is made through the skin on the clavicle—not above it—and it extends from the external attachment of the sternocleidomastoid muscle along the clavicle for an inch or even two, for I find it advisable sometimes to carry the inner portion of the approach a little mesial to the edge of the muscle. With careful blunt dissection and resection, the subclavian triangle is exposed. One retractor above and one mesial are necessary but no retraction is required below because the clavicle is, of course, immovable. The nerve will be seen on the anterior scalene muscle running downward and inward. It should be bluntly raised and a few drops of the anesthetic solution injected into it. I usually follow this injection with a few drops of alcohol. The alcohol is injected in order to infiltrate as much as possible the nerve below the point of section in case too short a piece should be removed by avulsion, so that there will be at least an interruption of a considerable part of the nerve. The nerve is then divided in the upper part of the wound, and the lower part is caught in the usual manner and twisted out. The skin is closed with a few metal clips or fine sutures, and if there has not been rough dissection no drain is required. If, however, there has been hemorrhage or if considerable manipulation has been necessary, I use a temporary drain with a split rubber tube to be removed in forty-eight hours. My dressing is a light pad of gauze over the wound itself and a thick pad in the supraclavicular fossa. This is held in place with a strip of adhesive plaster running from the front of the chest obliquely across the shoulder almost to the spine. If elastic adhesive plaster is at

Fig. 3—Complex type of phrenic nerve with four main stems. Dangerous relations with cervical arteries and subclavian vein. Difficult or impossible of avulsion.

hand, it will assure a springy dressing, comfortable and safe.

To those who are interested in the variations of this nerve I would recommend studying the paper by Matson¹⁴ with its beautiful drawings, two of which

are here reproduced by permission of Dr Matson (figs 2 and 3)

In addition to the anomalies that have been described in the literature, there is one that I have twice encountered, namely, the situation of the nerve far beneath the fascia covering the muscle and between the deeper fibers of the scalenus itself

The size of the phrenic nerve varies much. I have seen it as small as a thick horsehair and in one instance so large that had I not been able to identify it by the patient's subjective sensations I might have thought I was dealing with another nerve, in spite of its characteristic location

This is not the place to discuss the details of therapeutic effects of the operation, it would take too much time and space. I may state, however, that the low approach to the nerve which I have described makes it less likely that accessory nerve connections will be ignored even though these branches are not seen

By examining Dr Matson's pictures it is quite evi-

dent that no matter what operation is done there are opportunities for failure or accident, the most serious one being injury to the subclavian vein. The low exposure that I advise has made it possible to see this vessel and form an idea of what is happening to it during the avulsion of the nerve

I have three times injured the thoracic duct where it enters the subclavian or internal jugular vein, but in none of these cases was there the slightest trouble because of leakage. A small packing firmly compressed by the subsequent dressing was removed in two days with no further leakage. It should be mentioned here that in the cases in which violation of the thoracic duct has been followed by leakage and starvation there has been malignant or inflammatory disease, with dense infiltration of the surrounding tissues, preventing the collapse of the injured duct

Recently an attempt has been made to produce a depression of the first and other ribs by section of the scalene muscles. I mention this merely because it is a modern operation and comes under the title of this paper. It does not appear to me to be of any real value when compared with the other methods at our disposal, especially the later forms of apicolysis. Brown and Atkinson¹⁵ in a recent estimate of the value of this procedure are of the opinion which I have just expressed and the conclusion they have reached is that "although scalenotomy is relatively simple and feasible, the clinical results obtained thereby do not warrant its performance"

After all, it must be remembered that when the first rib has been resected posteriorly, even though only a small part of the bone has been taken away, there is tremendous dropping and rotation of the remainder of the rib so that it becomes almost parallel with the long axis of the body (figs 4 and 5)

¹⁵ Brown A L and Atkinson Kathleen. *Am Rev Tuberc* 28: 176 (Aug) 1933

Another extrathoracic method for lessening the capacity of the pleural space is the production of pneumoperitoneum by which both diaphragms are pushed upward. This is particularly applicable in bilateral disease¹⁶

It has been noted that in tuberculous women when the terminal months of pregnancy have filled the abdomen and forced the diaphragm upward there is improvement in the pulmonary condition and that after the confinement the return of the phrenic domes to their normal position has been followed by manifestations of recrudescence of tuberculosis

I have not made use of pneumoperitoneum for this purpose although I have frequently employed it in the roentgen diagnosis of diaphragmatic hernia. I am therefore unable to speak from personal observation

I have found it prudent not to paralyze the diaphragm before the induction of pneumothorax and have been able to demonstrate clearly by roentgenograms that the paralyzed diaphragm is pushed downward by a moderately tense pneumothorax, until it reaches the normal level¹⁷

Alexander¹⁸ has devised a method for lessening the excursion of the ribs in respiration by dividing (or otherwise blocking) the intercostal nerves. He does not necessarily reserve this procedure for patients who are so feeble that they cannot withstand thoracoplasty, although he has performed it in cases of this kind. The suggestion is interesting but it does not appeal to me, since it is intended to produce rest alone, with only a minimal lessening of the capacity of the pleura. It probably has its application but the cases must be rare. Then, too, there follows a disagreeable numbing of the

Fig 4 (Mrs Bessie S.)—Before operation: cavitation of right upper chest

Fig 5 (same case as in figure 4)—After thoracoplasty, illustrating good apical compression although the first rib has been merely divided, not resected. Observe its almost vertical position

cutaneous sensations in the distribution of the divided nerves which is not encountered in thoracoplasty, for no nerves are here blocked or divided. Alexander makes no mention of hemiparalysis of the abdominal muscles, which are supplied by the six lower intercostal

¹⁶ Vajda Ludwig. *Pneumoperitoneum in Bilateral Pulmonary Tuberculosis*. *Ztschr f Tuberk*. 67: 371 1933

nerves. Were these nerves merely cut, the muscular function might return, but with resection or even avulsion this would seem impossible. It is difficult for me to conceive of a patient so ill that when an operation of any kind is considered he could not endure a carc-

Fig. 6—Maurer's incision beginning below the spine of the scapula. Application of Elastikon to compress lower resected ribs.

fully graded thoracoplasty in local anesthesia. After all, there must be a well functioning contralateral lung to secure success. Here again it is hardly fair for me to express an opinion, since I have never performed the operation. It is mentioned merely for the sake of completeness and because of the important experimental quality of the work.

OPERATIONS ON THE BONY THORACIC WALL

The standard methods of Estlander, Bruer, Sauerbruch and others will be discussed here only in their recent modifications. First, as to the skin incision in paravertebral thoracoplasty. One of the disadvantages, especially in the case of a female patient, has been the extension of the scar high up on the shoulder. Recently Maurer¹⁹ has changed this so that the upper limit of the scar is below the spine of the scapula. By proper retraction upward it is perfectly feasible to resect the upper ribs, including the first. This leaves a space of unmarked skin, permitting the patient to wear a gown with a V shaped neck (fig. 6).

Probably the most frequent cause of early postoperative death, though the accident may not always have been recognized, has been the impairment of respiratory and cardiac function in the contralateral lung by bandages that encircle the chest. No bandage or binder, no matter how loose, should be permitted to envelop both sides of the chest.²⁰ The surgeon himself should apply the dressing immediately after the operation by holding a narrow gauze covering in place with adhesive plaster, which should not pass farther on the well side than the spine and in front to the distal edge of the sternum. The lower half of the thoracoplasty

may, however, be held firmly by adhesive plaster, passing from the midthoracic spine obliquely downward and forward across the abdomen to the opposite bony pelvic region (fig. 6). Compression of the diseased side can thus be secured without the slightest impediment of the motion of the opposite hemithorax. For this purpose I use a wide strip of the heavy adhesive strongly elastic material known by the trade name of Elastikon. To the ends of this material pieces of ordinary adhesive plaster of equal width should be stitched to prevent the edges from curling up. A support of this kind may be left in place for many days and the dressings can be changed by lifting the plaster away from the gauze beneath.²¹

The various splints and braces that have been recommended for this purpose are to my mind too complicated and uncomfortable.

In posterior thoracoplasty, a few points worth remembering are the following:

Occasionally the compression or collapse may not appear to have been successful even after a few months, the ribs uniting by bony bridges from end to end instead of dropping downward as they should. Hedblom, Alexander and others have advised that in these cases other resections be made through a longitudinal anterior axillary wound (fig. 7). I have made use of this method a number of times with success and a paper on the subject was almost ready for publication when Alexander's²² article appeared. The method is a good one but the second incision is not necessary as a routine. Years ago I operated in several cases by incisions through the original posterior scar, an almost bloodless procedure. The anterior parts of the ribs

Fig. 7—Axillary incision for removing more rib anteriorly after paravertebral thoracoplasty.

were thus easily found by dissection and anterior retraction. It has not been difficult for me to take away as much bone as I desire, even to the costal cartilages, without the complication of a second incision.

²¹ The part of the plaster next to the gauze may be prevented from sticking by powdering before it is applied.

²⁰ This matter will again be referred to in the discussion of apicolysis.

and with complete mechanical success (figs 8 and 9) Since I have not seen this secondary procedure elsewhere described, it is probably original

Sometimes there is striking improvement and even disappearance of bacilli after an operative result not anatomically perfect This is doubtless brought about by a stiffening of the thoracic walls with consequent rest Further thoracoplasty may be considered if symptoms of disease recur

Another procedure that I find to be a decided improvement on the older methods is the combination of posterior apicolysis with first stage thoracoplasty,

Fig 8—Insufficient collapse because of too rapid bone formation from periosteum between rib ends

Fig 9—Same case Three years after further resection of anterior portions of ribs through the scar of the thoracoplasty Unfortunately the patient now has disease in her other lung (The sides of this illustration have been reversed)

the anterior and axillary routes being avoided I now regularly perform posterior apicolysis at the first session in thoracoplasty I make the original incision downward and then around the scapula, which is finally mobilized (figs 10 and 11) The operator can carefully strip away the apical parietal pleura, push the lung downward and effect the compression of any ordinary cavity in this region Those with calcified walls will be referred to later

Rather than use a wax, paraffin or other rigid filling for this extrapleural cavity, I much prefer a method, which I have several times described, namely, packing with crumpled rubber dam (Not rubber tissue, erroneously ascribed to me by Casper and Bruns²³) One end of the rubber dam packing is led out at the lower angle of the wound, the rhomboid muscles are firmly sutured and the skin is closed over all except the drainage opening below In from three to five days or longer, if the packing is well tolerated, the dam may be removed and replaced by a soft rubber tube of good size (about 30 French) There will be discharge for some time, but gradually healing of the extrapleural cavity by granulation will occur and the walls will be drawn in permanently obliterating the cavity There is no tendency for the lung to rise to its original place in the thorax Should thoracoplasty of the lower part of the chest be necessary, this can be done at another time through an incision connecting with the mesial part of the first one (fig 10)

In any operation for collapse or even compression of the whole or a part of a lung, signs of cardiac distress may appear because of dislocation of the mediastinum with its contained vital parts Cyanosis dyspnea or other alarming symptoms should be the signal for

removal of the packings or of the pressure from without Relief will almost certainly follow

The rubber dam packing will increase the volume of the extrapleural cavity in four days, from double to treble the size that was present at the end of the operation (figs 12 and 13)

TRANSPLEURAL OPERATIONS NOT ON THE LUNG

The commonest transpleural operation not on the lung is of course the induction of artificial pneumothorax This procedure is so well known that it is unnecessary to go into details The value of this therapy has been greatly enhanced by the brilliant invention of the operating thoracoscope by Jacobæus, with its comparatively safe division of adhesions which would otherwise nullify the effects of the pneumothorax The section of these adhesions by the electric cautery with its obscuring smoke and danger of infection or hemorrhage when pulmonary tissue happens to form a part of the adhesion has been largely supplanted by operating with a coagulation current, which is smokeless and which will minimize the hazard Several new instruments of this type have been devised, but the one that has impressed me most is that of Dr Louis R Davidson of New York It requires but a single opening through the chest wall instead of two (one for observation and one for the cautery)

It has been stated that adhesions in the posterior part of the pleural space are difficult to reach, especially those which are wide and flat I question that it is worth while to try to divide adhesions of this kind, and yet occasions may arise in which it may be justifiable When this cannot be carried out through a single thoracoscopic opening in the chest I would suggest that, as in Jacobæus's original operation, another opening more advantageously placed can be made for the purpose of dividing the adhesions under the guidance of the eye at the telescope in the original thoracic wall perforation Eloesser of San Francisco has gone so far as to divide adhesions, using the approach of actual wide thoracotomy

and closing the chest after the adhesions have been divided between ligatures It has always appeared to me that thoracoplastic procedures would perhaps be safer than this method and yet I can understand how even this radical step may eventually

Fig 10—A B incision for posterior apicolysis C D incision of continuation for lower thoracoplasty

prevent permanent loss of function in healthy lung, which might otherwise be sacrificed in destroying the function of the diseased part

The tendency of modern surgery is to conserve the breathing space of a lung when only part of it is hopelessly diseased

To return to the discussion of uncomplicated artificial pneumothorax, a special danger may be here mentioned I refer to dislocation of the mediastinum, to which I have already referred

A means for combating this annoying complication was recently called to my attention by Dr Herben of Loomis Sanatorium If deviation appears after the

²³ Bruns E H and Casper Joseph *Nat Surgeon* 68 311 (March) 1931

induction of pneumothorax of a comparatively low tension, it should be regarded as a danger signal and measures should be taken to stiffen the mediastinum before proceeding with any further collapse therapy. Berck²¹ has gone so far as to make experiments on the mediastinal space itself to produce rigidity, but this seems to be an operation of too great magnitude and peril. Dr Herben has shown that the injection into

Fig 11—After posterior apicectomy

the pleural sac of an aseptic irritating substance, such as gomenol and oil or liquid petrolatum alone, later to be withdrawn has a tendency to produce pleural thickening and the much to be desired rigidity.

Two contrasting cases of my own have impressed this strongly on me. The first patient, operated on years ago by thoracoplasty immediately after the procedure became cyanotic and in danger of death, loosening the adhesive plaster dressings relieved the condition, but

immediate perfect collapse was thereby prevented.

The other patient was a young woman on whom thoracoplasty had been contemplated but in whose chest Dr Herben recognized dangerous mediastinal mobility after only moderately tense pneumothorax. This was overcome by temporary oleothorax with gomenol. When the mediastinum became rigid I succeeded in achieving good thoracoplastic obliteration of the diseased lung, with final disappearance of all symptoms and with absence of bacilli from the sputum.

OPERATION ON THE LUNG ITSELF

I now come to the consideration of the more radical intrapleural measures. These are mainly operations on the lung itself and I shall mention first the direct drainage of cavities. There are two principal reasons why this should be performed. First it should be performed when the cavity harbors mixed infection which becomes dangerous to life. The mere presence of tuberculosis as a primary factor should not prevent the treatment of such a cavity as if it were a nontuberculous or even a putrid lung abscess. The first case in which I had recourse to this operation occurred a number of years ago. The patient had a large cavity in the upper central part of the right lung, and after the first stage of thoracoplasty there was high fever and great distress because, apparently, the compression of the thoracic wall had impeded emptying by way of a bronchus. Nearly three weeks later I realized that unless direct drainage was accomplished my patient would lose her life. Therefore, with considerable misgiving, I performed pneumonotomy and drained the cavity fearing, as was the general belief, that because of the tuberculosis the resulting fistula would become permanent. There was immediate relief and in due time the thoracoplasty was completed. Contrary to my fears the fistula closed and the cavity has had to be opened twice since then, the last time only a few

months ago when the entire roof was removed and the wound treated by packing. So long as the cavity is open the patient is comfortable but if it closes there is cough with distressing asthma. At the present writing the hollow seems to be obliterating naturally and I have great hope that this troublesome case will eventually terminate happily. At any rate the woman is alive and active nearly ten years after the original operation.

Since then I have opened other similar cavities and feel convinced that, when there is a great quantity of sputum and the surgical compression from without can not be attained, it is far safer in the presence of a healthy contralateral lung to drain freely through the chest wall rather than to subject the individual to the dangers of cough and probably spill-over infection.

In another instance, also years ago, there was an upper cavity with a tuberculous empyema with cough and profuse expectoration. Dr Amberson suggested that it might be worth while to drain the pulmonary cavity into the pleura. This was done with immediate improvement, but for other reasons this case has been a difficult one and I fear that the unfortunate patient is doomed to a sanatorium existence.

In contrast with these cases is the following:

L. Z., a man, aged 49, with glycosuria,²² which was under control with insulin, complained of a large right upper abscess of the lung. He had been treated by endoscopy and otherwise with no success and the abscess seemed to be rapidly progressing. Immediate drainage through the chest wall seemed urgent and I referred the patient to a hospital where he was out of my control, although I sent a note suggesting the

Fig 12—Diagram of action of apicectomy (in this case axillary). A cavity with a fluid level is compressed into a slit. A before operation. B immediately after operation. C four days after operation. The cavity is now obliterated and the extrapleural space much larger.

advisability of early operation. He was admitted to the medical service and on repeated bronchoscopic examinations tuberculosis was diagnosed and there was a delay of two weeks, after which spontaneous pneumothorax occurred. Operation was then performed and the cavity drained, but death occurred soon afterward.

²⁵ An interesting paper on the coincidence of diabetes and tuberculosis is that by Wessler and Hennell (*Am Rev Tuberc* 27:47 [Jan] 1933).

While I do not maintain that the fatality would have been avoided by earlier drainage, I do believe that delay in a case of this kind contributes to the danger and that the mere diagnosis of tuberculosis as a complication in abscess of the lung was of no importance in deciding on the character of the treatment to be adopted

Cavities with calcified or ossified walls but with large secreting surfaces with profuse expectoration, whether bronchiectatic, multiple or single, form a very serious and difficult class. The usual extrapleural operations are inadequate, and drainage through the chest wall may leave permanent disability.

At the 1933 meeting of the American Society for Thoracic Surgery, Dr. Harold Neuhoof presented a method for the collapse of those cavities in which it can be demonstrated that there is no free space between the two pleural layers. He incises the layers covering the abscess until he reaches a cleavage plane beneath which there is a collapsible wall. Then with careful manipulation he obliterates the cavity and holds the compression by packings, covering these with mobilized periosteum as well. While I have not attempted this procedure, I believe it may have an important place in thoracic surgery.

As a last resort, especially in the bronchiectatic cases, it seems to me that resection of the rigid walled cavity should be done either at one sitting or in divided stages according to the conditions encountered. Indeed, I feel that eventually resection of the lung will become one of the operations of recognized worth in certain cases of localized pulmonary tuberculosis. Thus far, though I have resected many pulmonary lobes for suppurative disease, I have not had the opportunity to apply the principle in cases of phthisis.²⁶

ELECTROSURGERY

Another new and important adjunct in operations on the chest wall is electrosurgery. When properly carried out the electric incision of the skin insures aseptic conditions unobtainable by the ordinary instruments. The tissues must be divided with a quick sure stroke, so that cell destruction along the walls of the wound may not be so great that healing will be delayed. There is another distinct advantage in the small number of hemostatic ligatures, the blood flow from vessels of small size being checked by coagulation through hemostatic clamps. I have performed a secondary complete paravertebral thoracoplasty with resection of ten ribs

without the application of a single ligature. There was primary union throughout. Those who are interested may care to read a recent article which I contributed on this subject.²⁷

Electrosurgery in thoracic disease should be confined to the chest wall, for if it is employed within the pleura and especially near the heart there is danger that the muscle of that organ may be made to contract abnormally, with fatal result.

EMBOLISM AND MASSIVE COLLAPSE

Among the dangers always to be considered in any operations on the chest for tuberculosis, two are outstanding. They are massive collapse of the better lung and cerebral air embolism. Bacterial embolism with metastasis to the brain is, of course, always possible, and there is no way in which this can be prevented. The danger of air embolism can be greatly diminished by keeping the patient's head lower than his chest during any operative procedure on the wall or cavities of the thorax. Massive atelectasis in thoracic surgery can be treated, but the accident cannot at present be prevented.

ANESTHESIA

With the appearance of tribrom-ethanol as a powerful preoperative hypnotic, a valuable agent is available which relieves the patient of mental anxiety and excitement and which, when properly given as an adjunct and not as a true anesthetic, becomes a genuine blessing in many operations on the chest. But there is one important contraindication, namely, the habitual expulsion of a large amount of sputum, for, in spite of the precaution of pharyngeal suction during operation, the long-continued sleep afterward is liable to be accompanied by aspiration into the better lung. Therefore I do not use tribrom-ethanol in any case when there is profuse expectoration.

SUMMARY

1 Tuberculosis as a disease is not amenable to surgical treatment. Anatomic conditions of a pathologic and threatening nature resulting from the disease may be treated by surgical procedures.

2 The chief object is the obliteration of tuberculous cavities and the conservation of healthy lung.

3 Operative procedures are divided into (1) extra-thoracic, (2) operations on the chest wall, (3) transpleural operations not on the lung, and (4) operations on the lung itself.

Fig. 13.—Posterior apicolysis five days after operation. Observe balloon with sodium iodide solution as a contrast medium for roentgenologic purposes. Tube emerges from lower angle of wound through which balloon may be filled, emptied and withdrawn.

²⁶ In 1913 Tuffier demonstrated to me the case of a young woman whose right apex he had resected by drawing it with its parietal pleura through the anterior chest wall, ligating its base, ablating the extruded part and dropping the stump back into the chest. When I saw her the woman had fully recovered.

Always a Sign of Syphilis—From a study of the literature and an examination of numerous cases of so-called non-syphilitic Argyll Robertson pupils, one can safely say that a real Argyll Robertson pupil is always a sign of syphilis until it is proved otherwise. If one holds that the true Argyll Robertson pupil has certain definite characteristics besides the loss of the light reaction many of these cases can be excluded because they do not come under the classification of a real Argyll Robertson pupil. In many of these reported cases the pupils were dilated and the convergence reaction was retarded. The reason for publication of these reports was the loss of the light reflex. Most writers on this subject hold that a real Argyll Robertson pupil has certain definite features besides the absence of the light reflex and agree with Bumke and Behr that such a pupil is always a sign of syphilis of the central nervous system—McAndrews, L. F. Argyll Robertson Pupil, *Arch Ophth* 10: 520 (Oct) 1933.

NICKEL CARBONYL POISONING

REPORT OF A CASE

W. W. BRANDES, M.D.
DALLAS, TEXAS

Intoxication with nickel carbonyl has been of rare occurrence. A number of cases that occurred in England, where the Mond process for obtaining pure nickel was first used, were reported some years ago.¹ Richter² reported a case of poisoning with metallic nickel, with recovery. Gron³ reviewed the subject of nickel rash and reported a case. Stewart⁴ recently has reported a case of dermatitis due to nickel and cobalt.

Armit⁵ some years ago studied the toxicity of nickel carbonyl and other nickel compounds on experimental animals and found that the nickel was the toxic element and not the carbon monoxide formed. The amount of carbon monoxide liberated on dissociation from a minimal lethal dose of nickel carbonyl was sufficient to give only a 5 per cent hemoglobin saturation, which is well below the lethal level for carbon monoxide.

Nickel carbonyl is prepared by passing a current of carbon monoxide over finely divided metallic nickel. A gaseous compound is formed with the composition of $\text{Ni}(\text{CO})_4$. The gas can be condensed into a mobile liquid, which boils at 43 C and volatilizes at room temperature.

Characteristic changes found in the cases reported were hemorrhages especially in the white matter of the brain and in the lungs, fatty degeneration of the walls of blood vessels, and edema of the lungs. In experimental animals hemorrhages were always found in the lungs, in the suprarenal glands in more than 50 per cent of cases and frequently in the brain. At

nickel are deposited on the respiratory epithelium and are absorbed by the blood stream, causing degenerative changes in the vessel walls. The nickel is gradually removed from the lungs and some of it, at least, is excreted by the kidney, since it has been found in the urine.

The outstanding clinical features were a transient malaise with rapid recovery when brought into fresh air. At times nausea and vomiting occurred early. After from twelve to thirty-six hours cyanosis and dyspnea developed and progressively increased in

Fig. 2.—Same area of lung as in figure 1 under high power. Disintegration, fusion and proliferation of alveolar epithelium are seen more clearly. Hematoxylin and eosin stain.

severity. A productive cough with blood stained sputum was frequently observed. Death occurred between the fourth and eleventh days.

REPORT OF CASE

C. B., a white man, aged 49, complained of dyspnea, orthopnea, nausea, vomiting, insomnia, pain in the right side of the thorax, headache and a metallic taste in the mouth. A chemist by profession, he had been working on a problem of developing a method of "cracking gasoline," in which process nickel carbonyl was used. The present trouble developed five days previous to admission to the hospital. At that time he had poured nickel carbonyl from one container to another and immediately thereafter experienced some dyspnea from which he recovered after a brief interval. About twenty-four hours later, dyspnea recurred. He became orthopneic and cyanotic, so that at times he would "turn black." By the fourth day he became nauseated, vomiting occurred, which became increasingly severe, so that very little food could be retained. Several of his associates had mild attacks of dyspnea but quickly and completely recovered.

The physical examination revealed marked cyanosis and great respiratory difficulty. The pupils reacted normally. The tongue had a grayish coating. A firm nodular movable mass 4 by 5 cm was palpated on the right side of the neck, below the ear. Expansion of the right side of the thorax was limited and moist rales could be heard in the middle and lower lobes anteriorly and posteriorly. Tactile and vocal fremitus were increased in these areas. The heart was within normal limits, the pulse was regular and the rate was 100. The liver edge could be felt 4 cm below the costal border. It was slightly tender. The extremities were normal, except that the reflexes were hyperactive.

Laboratory reports revealed that the blood count was 5,100,000 red cells, hemoglobin (Tallqvist) 100 per cent, and the white cell count 15,800, with 92 per cent polymorphonuclears, of which 21 per cent were band forms. The plasma carbon dioxide combining power was 60.5 volumes per cent. Sputum was blood streaked and tenacious in character. The urine contained a few hyaline casts and a trace of albumin.

The patient had great respiratory difficulty, was very restless became comatose and died on the seventh day after exposure to the nickel carbonyl.

At necropsy there was slight icterus of the sclerae and a faint greenish yellow tinge to the skin of the face, neck and anterior thorax. The lips and oral mucosa were deeply cyanotic. Below the right ear was a nodular mass 3 by 5 cm that was freely movable. In the skin of the back were numerous dull reddish areas from 1 to 5 mm in diameter. The pleural cavities contained about 15 cc of clear fluid, their linings were everywhere smooth and glistening. Numerous dark red areas measuring from less than 1 to 5 mm in diameter could be seen through the pleurae of both lungs. The left lung was voluminous and heavy, a reddish gray, and mottled with numerous darker red areas scattered throughout. The main bronchus and larger branches contained a frothy reddish fluid, and the lining was bluish red. Large amounts of blood-stained fluid escaped from the sectioned surfaces of the lungs. The greater portion of the left lung was noncrepitant. The right lobe similarly was heavy and dark reddish gray. The cut surfaces were very wet. The greater portion of this lung was also noncrepitant. The pericardial cavity contained about 15 cc of clear fluid, and the lining was smooth and glistening. The right heart chambers were distended with partially clotted dark venous blood. The endothelial surfaces were smooth throughout. The apex of the left ventricle was slightly sacculated. Several small plaques of yellowish thickening were present in the bases of the aortic and mitral valve cusps. The myocardium was grayish red with small yellowish red and dark red widely scattered areas in it. The heart weighed 480 Gm. The proximal 2 cm of the right coronary artery showed a diffuse yellow thickening of the intima with slight narrowing of the lumen. The first portion of the aorta had small areas of yellowish thickening of the intima, which increased to a moderate degree along the course of the vessel.

The liver weighed 2100 Gm, its capsule was smooth and the edges were slightly rounded. On sectioned surface the lobular markings were accentuated. The peripheral portions

most numerous in the white matter, especially of the corpus callosum. They varied in size from those barely visible to a centimeter in greatest dimension. The majority were dark red, a few were brownish red. Some were elongated in outline. These small areas could be seen in the pons and the basal nuclei, and several small indefinite darker grayish areas were present in the medulla.

Fig 4—Higher magnification to show degenerative changes in ganglion cells and neuronophagia. Cresyl violet stain.

Fig 3—Demyelinated areas in the base of the brain. One has a vessel in the center. Weil's myelin sheath stain.

of the lobules were yellowish gray. The kidneys together weighed 380 Gm. The surfaces, after stripping of the capsules were finely granular. The cortex was of average width. The pyramids were dark red. The spleen was slate blue and its capsule was smooth. Sectioned surface revealed scattered throughout irregular dark red areas. Other viscera showed general passive hyperemia and small widely scattered areas of hemorrhage.

No changes were seen in the dura. The spinal fluid was clear. The meningeal veins were prominent. The dural sinuses contained dark venous blood and had smooth linings. The cerebral ventricles were not noticeably dilated. They contained a few cubic centimeters of faintly blood-tinged fluid. On multiple transverse sections numerous dark red areas were present

Histologic examination revealed that the changes in the lungs and brain were most marked and most important in this case. Sections taken from the noncrepitant areas in the lungs (fig 1) revealed a marked edema, hyperemia, multiple hemorrhages and marked changes in the cells lining the alveoli. A slight to moderate infiltration with polymorphonuclear cells was seen. The alveoli were distorted and many to most of the lining cells had become desquamated. Many were markedly swollen and had granular cytoplasm, and others showed fragmentation. Some of the alveoli contained large cytoplasmic masses with multiple nuclei and nuclear fragments (fig 2). These masses seemed to be fused degenerated lining cells. Some of the alveolar epithelial cells stained deeply, and mitotic figures were fairly frequent in some areas. A number of small blood vessels contained fibrin thrombi in their lumens, and their walls were indistinct. There was a large amount of granular vacuolated precipitated albuminous material in the interstitial tissues and in the alveoli. The epithelium of the bronchi and bronchioles also showed degenerative changes. They were swollen and some desquamation had occurred. Many of the mucosal glands were distended with secretion.

Histologic examination of the brain revealed multiple small hemorrhages scattered throughout but most numerous in the white substance. The majority were small and in perivascular areas. Aside from the hemorrhages multiple small areas of degeneration were scattered throughout, which showed demyelination with a myelin sheath stain (fig 3). These at times were about capillaries and arterioles. In some of these areas, moderate numbers of polymorphonuclear and large mononuclear cells could be seen. The hemorrhages varied somewhat in that in some the red blood cells were intact, whereas in others they were partly disintegrated. In a fair number of capillaries and arterioles hyaline and fibrin thrombi were seen. The walls of some of the arterioles were indistinct and more or less homogeneous and hyaline-like in structure. Ordinary fat stain did not show an increase in fat. With cresyl violet stain degenerative changes were well demonstrated in many ganglion cells. Some of these were greatly swollen. In others

the Nissl granules had disappeared, especially in the perinuclear areas, and the nucleus in some was eccentric in position. Neuronophagia of some of these cells could be seen (fig 4).

Thrombi were also found in the myocardial vessels (fig 5). Other viscera, such as the liver, kidney and spleen, showed passive hyperemia and rather marbled parenchyomatous and fatty degeneration (liver) but no distinctive changes. The mass in the neck proved to be a mixed tumor of the parotid gland type.

Specimens of tissue from the brain and lung were examined for nickel, dimethylglyoxime being used for the development of a color reaction.⁷ This test is of sufficient sensitivity to demonstrate the presence of 0.001 mg. of nickel. The extract from 3 Gm. of lung gave a strong test, bright red. Three grams of brain tissue gave a much weaker but a very definite pink red. The same method was used in testing 4 Gm. of tissue from the brain in a case of meningitis which gave no color change, the solution remaining colorless by contrast. Blood examined post mortem failed to give a test for carbon monoxide.

SUMMARY

The clinical and pathologic features of this case correspond closely with those of the cases previously reported. The histologic changes in the lung are quite

Fig 5.—Thrombus in a vein in the myocardium. Hematoxylin and eosin stain.

unusual and correspond more nearly with descriptions of observations in the lungs damaged by irritating substances such as phosgene. The changes in the capillaries and arterioles explain the presence of multiple small hemorrhages, also the degenerative changes and areas of anemic necrosis in the brain. That these changes are due to the nickel is indicated by the presence of this metal in relatively large amounts in the tissues analyzed. The lesions were not the result of carbon monoxide present, since at that early stage, seven days, sufficient carbon monoxide should have been present to give a positive test if it were the substance that had caused the widespread lesions. Furthermore, carbon monoxide does not cause the type of lesion in the lung present in this case. Armit⁸ demonstrated that the nickel appeared to be transported in the blood in a condition of colloidal solution. The metal is gradually absorbed from the lung in animals poisoned with nickel carbonyl, to such a degree that recovery is possible. The symptoms of extreme dyspnea, nausea and vomiting, restlessness and hyperactivity of reflexes may in part at least have been due to the cerebral lesions.

OSTEITIS TUBERCULOSA MULTIPLEX CYSTICA OF FIBULA AND TIBIA

SAMUEL SANES, MD

AND

WARREN S. SMITH, MD

BUFFALO

Following its introduction by Jungling¹ in 1920, the term "osteitis tuberculosa multiplex cystica" was applied to cystlike degeneration of the bones without joint involvement, characterized by the gradual onset of mild pain and swelling of the affected parts, distinctive roentgenographic observations and a chronic benign course. Not infrequently associated were lupus pernio and Boeck's sarcoid. Histologically, the bone showed epithelioid and giant cell tubercles, with little or no caseation. Tubercle bacilli were rarely demonstrated in examined tissue, guinea-pig inoculation occasionally gave positive results for tuberculosis.

In the past year Van Alstyne and Gowen,² reviewing the literature on osteitis tuberculosa multiplex cystica, stated that in all the reported cases the condition was restricted to the small bones of the hands or feet. There was the first authentic case presenting typical lesions in the long bones. They presented a white man, aged 32, who exhibited destructive changes in the left ulna, the left radius, and both humeri. A tuberculous etiology was proved by histologic and bacteriologic methods, and by guinea-pig inoculation. Because of its rarity, verified histopathology and diagnostic support, we record an additional case of osteitis tuberculosa multiplex cystica of the long bones.

REPORT OF CASE

E. S., a white American woman married aged 56, admitted in the service of Dr. W. W. Plummer, Sept. 2, 1932, complained of pain and swelling of both lower legs of three months' duration. At the age of 30 the patient had had typhoid. Her father and daughter had died of pulmonary tuberculosis, one brother was suffering from the same disease.

During July, 1932, the patient had noted swelling and pain in both lower legs. In a short time the symptoms in the left leg subsided appreciably. The pain in the right leg, however, persisted as a dull ache, which was intensified when the patient was walking or when the leg was bumped. There was no history of trauma or loss of weight. The chest was clear. The inguinal lymph nodes were not enlarged. Slight swelling and tenderness were found over the lower end of the right fibula. The right ankle showed no pain or limitation of motion.

The left leg was not remarkable. The temperature ranged between 98 and 99 F., the pulse was 80 and the respiration rate was 20. Laboratory examination showed hemoglobin 90 per cent, leukocytes, 9,700 per cubic millimeter, urine normal. The Kahn test was negative. Roentgen examination (Dr. E. C. Koenig) of the lower legs and feet revealed in the right fibula about one-half inch above the top of the astragalus decreased density of the bone tissue with a more or less oval excavation, which was cystlike in appearance. There was a thickening of the periosteum on the outer side of this cystlike excavation. Otherwise the bone tissue of the right tibia and fibula was well within average limits. The right foot, left foot and ankle did not show any evidence of bone disease comparable to that in the right fibula. Examination of the chest indicated increased density of lung markings, especially in the right interscapular region, with small calcareous deposits.

At operation (Dr. F. N. Potts), September 25, a small area of destruction was found in the lower end of the right fibula.

From the Pathological Laboratory and Orthopedic Department, Buffalo General Hospital and University of Buffalo School of Medicine.
¹ Jungling, Otto. *Fortschr. a. d. Geb. d. Röntgenstrahlen* 27: 3, 1920.
² Van Alstyne, G. S., and Gowen, G. H. *J. Bone & Joint Surg.* 15: 193 (Jan.) 1933.

filled with an abundance of red granulation tissue. The soft tissues appeared normal, no joint involvement could be made out.

The surgical specimen was decalcified and examined in paraffin sections by hematoxylin-eosin, Van Gieson, Ziehl-Neelsen, and Gram-Weigert stains. Only a few remnants of fat marrow bordering bone trabeculae were noted. The medullary cavity was replaced by chronic granulation tissue composed of solitary and conglomerate epithelioid and giant cell tubercles. Extensive lymphocytic and plasma cellular infiltration was present. A few tubercles showed necrosis, in places, fibrosis was taking place. The haversian canals were enlarged. Bone trabeculae were atrophic and fragmented. The endosteal surfaces were not smooth and intact but showed everywhere shallow and deep lacunae, apparently eroded by the spread of vascular granulation tissue. Osteoclasts were not seen. The bone itself was also perforated by canals with a central vessel and ragged borders. Here and there small sequestrums lay free with no special reaction about them. No new bone formation was made out. There was no definite cyst wall. Tubercle bacilli could not be demonstrated by bacterial stain. The histologic diagnosis was tuberculous osteomyelitis with inflammatory osteoporosis (caries).

Postoperatively, two roentgen treatments were given to the right leg. On the patient's discharge, October 30, the operative wound was healed, clean and dry.

After the patient had been home for a week, distinct swelling and pain appeared in the left lower leg. On admission to the hospital, November 18, swelling and tenderness were elicited over the left internal malleolus. Except for a healed scar, the right lower leg was not remarkable. Roentgen examination of both feet and ankles showed in the left tibia decided reduction in the density of bone of the internal malleolus in several circumscribed irregular areas. The overlying periosteum was distinctly thickened. The bone tissue of the left foot and ankle was well within average limits. The right fibula showed that the former cystlike cavity had smooth walls and a clean cut outline. December 9, an incision was made over the internal malleolus of the left tibia. The subcutaneous tissue and periosteum were injected. In the bone of the lower end of the tibia was a small cavity filled with soft, hyperemic spongy material. The adjacent joint was free. Histologically, the excised soft tissue and bone showed chronic granulations with

so-called osteitis tuberculosa multiplex cystica of the long bones. Mild pain and swelling, which developed gradually in both legs, were the chief complaints. A definite family history of tuberculosis, and indicative manifestations of old pulmonary tuberculosis in the patient were present. The temperature reached 99 F in the afternoon. Destructive cystlike changes in the right fibula and left tibia, of outspoken character in the former, were demonstrated by roentgen examination. In neither leg were the ankle joints, the small bones of the feet or the skin involved. Operation

Fig 3—Epithelioid and giant cell tubercles atrophic and fragmented bone

revealed in both fibula and tibia small "cavities" filled with spongy granulation tissue, in the left leg, the periosteum and the soft tissue were hyperemic. Excised bone showed histologically tuberculous osteomyelitis with epithelioid and giant cell tubercles, but with practically no caseation. Tubercle bacilli were not found by bacterial stains.

Analysis of its anatomic and pathogenic features suggests that the condition here cited might more accurately be designated "osteomyelitis tuberculosa multiplex cystoides." The primary lesion is a tuberculous osteomyelitis. From a focus elsewhere in the body, infecting organisms are carried to the bone marrow by the blood stream. Regressive changes in bone trabeculae occur secondarily to the spread of granulation tissue in the marrow cavity and haversian canals. Before bone destruction and resorption can be demonstrated roentgenographically, considerable time must elapse. For example, our patient complained of definite symptoms in the left leg four months before periodic roentgenograms first showed decreased density of the bone. It may be further reasoned that even a longer time must ensue before regressive bone changes become extensive enough to produce roentgenographically distinct cystlike excavation. So-called osteitis tuberculosa multiplex cystica represents, then, merely a late phase of chronic localized tuberculous osteomyelitis, the diagnosis of which, as of acute nonspecific osteomyelitis, may be suspected before roentgen signs are evident. The term "cystica" appropriately describes the roentgen picture alone. The actual lesion is a circumscribed area of soft granulation tissue and degenerated bone which only on curettement is converted into a cystlike cavity. A definite capsule cannot be made out. With the absence of marked caseation no pseudocyst or cavity can be said to form. In fact Jungling³ in his last studies abandoned his original term "cystica" for "cystoides."

Fig 1—Cystlike cavity in right fibula before operation

Fig 2—A right fibula after operation B decreased density in circumscribed areas of left tibia

epithelioid and giant cell tubercles, also present were several small abscess-like foci made up of polymorphonuclear leukocytes, many of which showed pyknotic nuclei. Giant cell tubercles seemed fewer than in the first specimen. The wound healed within twelve days but broke down three weeks later draining thin serous fluid. Three roentgen treatments were given to the left leg. The patient was discharged to the Charity Hospital, Washington, D C.

COMMENT

From a clinical roentgenographic and pathologic basis this case can be justly considered as one of

Opposed to the benign circumscribed, fungoid type of bone tuberculosis with practically no erosion, here described must be placed that form with diffuse spread and extensive caseation, sometimes necessitating the surgical removal of an entire long bone.⁴ Among the causes of chronic destructive bone lesions of multiple and focal character such as syphilis, leprosy, osteitis fibrosa cystica, giant cell sarcoma, coccidiosis, echinococci, cysts, nonspecific osteomyelitis, multiple myeloma and metastatic malignancy, so-called osteitis tuberculosa multiplex cystica should be considered.

Because of the benign course and tendency to spontaneous recovery, no definite treatment has been recommended for the disease in question with the exception of symptomatic measures and immobilization. Jungling⁵ entertained the possibility of surgical excision of cystlike areas but made no application of this method. It is too early to evaluate the results of surgical and roentgen therapy in our case.

PULMONARY MONILIASIS

HENRY J. BAKST, MD

J. BEACH HAZARD, MD

AND

JOHN A. FOLEY, MD

ROSTON

Three cases of pulmonary moniliasis came under observation in the Fifth Medical Service of the Boston City Hospital during November 1932. One was an infection secondary to pulmonary tuberculosis, the other two were primary infections. Because of the confusing symptomatology the excellent results obtained with treatment and the sparseness of cases in American literature, it is believed that this report is warranted.

Castellani's¹ early description of bronchomoniliasis was that of a disease closely simulating the clinical picture of pulmonary tuberculosis. Subsequent papers by various authors, however, described several other clinical manifestations of monilia infections of the lungs and bronchi. In addition to the often stressed resemblance to pulmonary tuberculosis—also tracheobronchitis,² lobar pneumonia,³ bronchopneumonia and bronchial

asthma⁴ have been reported as the result of monilia infections of the respiratory organs. Although Castellani first focused attention on the fact that monilia may be the primary etiologic agent in bronchopulmonary disease, it is also well recognized that this organism may be a secondary invader in the air passages of individuals infected with some primary bacterial agent.⁵

Primary bronchopulmonary moniliasis has been divided into three clinical types⁶ a classification based chiefly on the severity of the infection. The mild type is associated with cough and mucopurulent sputum. Examination of the chest in these cases is often negative, but it is not unusual to find a few scattered rales. The clinical course frequently extends over a period of several months at the end of which time these patients may recover spontaneously or the case may go on to the severe type. The intermediate or moderate type presents the picture of bronchial catarrh. Fever, cough, paroxysmal dyspnea and blood-streaked sputum are commonly observed. On physical examination, signs consistent with chronic bronchitis are usually found. Cases of this sort may persist in showing signs of activity for years or may go on to the severe type. This third type often has a history which strongly resembles that of pulmonary tuberculosis. Fever, loss of weight, night sweats, fatigue, chest pains, cough, hemoptysis, dyspnea and anemia are usually present. Examination of the chest may reveal signs of pleural thickening or consolidation. These cases, frequently, are fatal.

The acute case may have a sudden onset of symptoms with a rapid progression to a fatal termination. The chronic case is usually insidious in its onset and tends to follow a protracted course with frequent remissions and exacerbations.⁷ Cases of this type have been followed over a period of ten years.¹⁰

Bronchopulmonary moniliasis has been reported from practically all parts of the world.¹¹ It seems, however, that the maximum incidence is found in warm moist climates.¹² It is a disease that occurs chiefly in adult life, more often in males than in females.¹³

The association of monilia infection with chronic debilitating diseases has often been noted.¹⁴ The organisms have been found frequently as secondary invaders in pulmonary tuberculosis¹⁵ and neoplasms of the lung.¹¹

Monilia is usually found as a saprophyte. It is present frequently on putrescent wood, dead leaves and decayed fruit. It is thought by some¹⁶ that under

favorable conditions, this organism can become pathogenic for either man or animals. Primary infection in man is generally attributed to direct contact or inhalation.¹⁶ In debilitated individuals infection may result from the extension of oral or cutaneous lesions.¹⁶

The variations in the clinical picture have already been presented. The signs on physical examination are similarly variable except for the important fact that monilia infections tend to leave the apexes clear.¹² The

chest may appear normal, scattered râles may be present and frequently there are the physical signs of pleural thickening or consolidation.¹⁷ Fever may be absent, slight or moderate.¹⁸ There is usually some degree of anorexia and loss of weight.¹² A slight leukocytosis with an increase in eosinophils is common and there may be a relative lymphocytosis.¹⁹ A secondary anemia is a usual feature.¹² Roentgenologic studies may be negative or

Fig 1 (case 1)—Density in the left mid chest on admission

may reveal the presence of nodules, peribronchial thickening, areas of infiltration, consolidation, fibrosis or pleural thickening.²⁰ Usually the lesions are located in the bases of the lungs.^{11a}

For the treatment of pulmonary moniliasis, Castellani²¹ suggested the use of potassium iodide in large doses, from 30 to 60 grains (2 to 4 Gm) daily, in conjunction with creosote and glycerophosphates. Subsequent investigators have varied the treatment in resistant cases by modifying the form of iodide used and have achieved satisfactory results.²² Thymol by mouth,²³ gentian violet²³ and methylene blue intravenously²⁴ have also been used with fair results. Roentgen therapy is reported to be of considerable benefit.²⁵ Certain types of cases, however, apparently do not improve with any of these suggested methods of treatment. In such cases, the use of a vaccine has been recommended.²⁴ Insulin has been used to improve the appetite and to obtain a gain in weight.^{11a}

REPORT OF CASES

CASE 1—A white woman aged 21 single admitted to the Boston City Hospital Nov 10 1932 complained of a cough and increasing weakness for the preceding eight months. The cough was frequently productive of a blood streaked greenish or yellowish sputum. Three months after the onset of the cough she experienced frequent drenching night sweats and chills. She often felt warm and feverish late in the afternoon

or early in the evening. The menstrual flow, usually not remarkable, was definitely scanty during the two months previous to her admission to the hospital. For about the same period, she noted a distinct loss of appetite and, in the month previous to her entry, she lost 8 pounds (3.6 Kg). She fainted twice during the week preceding her admission.

The family and social history were essentially negative. No contact or association with tuberculosis could be established.

She had had the usual childhood diseases. At the age of 13, a physician advised her removal from school because she was 'run down' and her lungs had a few spots.²⁶ For three years afterward, her condition was followed at the outpatient department of a tuberculosis sanatorium for a question of early tuberculosis. For the next five years, until the onset of her present illness, she felt entirely well.

On admission to the Boston City Hospital, she was fairly well developed and well nourished but pale. Her chest showed diminished expansion on the left with slight dullness to percussion of the middle third posteriorly and inconstant crackling râles. Breath sounds were not remarkable. The right side of the chest was apparently normal. The heart was normal except for an apical systolic murmur. The systolic blood pressure was 90 and the diastolic 50. Examination of the urine was essentially negative. The hemoglobin was 70 per cent (Sahli) and the white blood cells numbered 10,800 per cubic millimeter of blood. A smear showed polymorphonuclear neutrophils, 64 per cent, lymphocytes, 25 per cent, and eosinophils 2 per cent, with no monocytes. The Kahn test was negative.

Of the twenty-six smears of sputum studied, none were positive for acid-fast bacilli, but thirteen were positive for yeastlike organisms. Cultures of the fungus were obtained from all of three sputum specimens after the mouth was carefully and thoroughly cleaned. Five blood cultures yielded no growth and one yielded a diphtheroid bacillus contamination.

A roentgenogram of the chest, on admission, revealed a mottled density in the left midchest, which was reported as either atypical tuberculosis or a fungous infection. Eight days later, a roentgenogram still showed slight density in the left midchest. December 6 thirty-seven days after admission, the lung fields were within normal limits.

A skin test with monilia antigen was performed, December 2, the fungus isolated from the patient's sputum being used, and 0.1 cc of a solution containing 500,000 heat-killed organisms per cubic centimeter being injected intracutaneously. An area of erythema, 1 cm in diameter, appeared in a few minutes, reached its height in an hour and disappeared at the end of three hours.

The patient's temperature was not remarkable except for an occasional afternoon rise to 99 F, except for December 20, when it rose sharply to 100.4 F and dropped to normal the next morning. The pulse rate was essentially normal and the respiratory rate varied from 20 to 25 a minute.

The patient was given a high caloric diet, elixir of terpin hydrate and codeine 15 grains (1 Gm) of potassium iodide three times a day and 5 grains (0.3 Gm) of creosote once a day.

At the end of about six weeks she showed considerable subjective and objective improvement but was not entirely well. Although examination of the chest revealed no positive

Fig 2 (case 1)—Lesion in chest entirely cleared four months after discharge

changes, she still had a slight cough and was moderately apathetic and listless, and the yeastlike organisms persisted in the sputum.

She was discharged, December 24, and after three days returned for vaccine therapy. On her second entry, the stools and urine were normal. The hemoglobin measured 80 per cent (Sahli) and the white blood cells numbered 8000 per cubic millimeter of blood. Yeastlike organisms were still present in the sputum.

The vaccine consisted of a suspension of a loopful of a pure culture of the monilia isolated from the patient's sputum in 3 cc of saline solution heated at 65 C for one hour. Therapy was instituted by injecting 0.1 cc of the vaccine subcutaneously. Thereafter the dose was increased by 0.1 cc and was given subcutaneously at intervals of three or four days. No general reactions were encountered but the local reactions were fairly constant. These consisted of an area of erythema from 2 to 5 cm in diameter which reached its maximum between twenty-four and forty-eight hours after injection and soon after this began to fade. The reactions were accompanied by considerable induration, pain and tenderness.

Agglutinations performed before vaccine therapy showed a positive reaction with a serum dilution of 1:20 and a negative one with 1:40. During the middle of the course of vaccine treatment a positive reaction was obtained at 1:80. At the end of the vaccine therapy agglutination was positive at 1:20 and negative at 1:40. Intracutaneous injection, at this time of 0.1 cc of a nucleoprotein fraction of the monilia recovered from the patient's sputum produced an area of erythema 2.5 cm in diameter in five hours, which disappeared twenty-four hours later.

The patient was discharged during the last week of January 1933. She has been seen four times at monthly intervals since her discharge and has continued to feel entirely well. The cough has been absent and

Fig. 3 (case 1)—Clumps of Monilia in the sputum showing thick hyaline coats and single and budding forms. (The photomicrograph was made by Dr. Frank B. Mallory.)

examination of the chest has been negative. Yeastlike organisms have been absent from the sputum. A roentgenogram of the chest, taken five months after discharge, was negative.

CASE 2—A white woman, aged 60, married, admitted to the Boston City Hospital, Nov. 24, 1932, complained of cough and shortness of breath for the preceding ten days. November 14, the patient suddenly noted the onset of chills, fever and cough. The cough at first was harsh, rasping and nonproductive, but at the time of entry to the hospital it was definitely productive of a thick greenish, mucopurulent sputum. The shortness of breath was definitely worse for the four or five days preceding admission. The patient felt most comfortable at night when sleeping sitting upright in bed. No history of hemoptysis or pain in the chest was obtained.

The family history, occupation and habits were not remarkable.

The past history was essentially negative except for an attack of bronchitis, sixteen years before admission.

On entry to the hospital, physical examination showed that she was well developed and well nourished, was uncomfortable lying in bed, and was markedly dyspneic. The lips were

cyanotic. The mouth showed no ulcerations or exudate. The tongue was red and dry and the pharynx moderately injected. Examination of the lung showed coarse crackling rales, moderately impaired resonance and increased breath sounds in the lower third of both sides of the chest. The peripheral vessels showed slight arterial thickening. The systolic blood pressure was 145 and the diastolic pressure 82.

The urine was not remarkable, except for a very slight trace of albumin and many white cells in one specimen. Culture of a catheter specimen of the urine showed no growth. Examination of the stools was negative.

The hemoglobin was 80 per cent (Sahli) and the white blood cells, on entry, numbered 11,900 per cubic millimeter of blood. A differential count showed polymorphonuclear neutrophils 76 per cent, lymphocytes 20 per cent, monocytes 4 per cent, and eosinophils 0 per cent. Five blood cultures were taken, three of which showed no growth, one was contaminated with *Bacillus subtilis* and another with diphtheroid bacilli. The Kahn test was negative.

Twenty-one specimens of the sputum were examined. The material was seromucoid to purulent in character. No acid-fast bacilli were found on smear. Polymorphonuclears were fairly frequent and eleven specimens showed the presence of yeastlike organisms. Cultures taken from three carefully obtained specimens of the sputum all showed the fungus.

December 2 a skin test was done with organisms obtained from cultures in case 1 and killed by heating to 65 C for one hour. One-tenth cubic centimeter of a suspension containing 500,000 organisms per cubic centimeter was injected intracutaneously. This resulted in a painful wheal at the site of inoculation 2 cm in diameter with an erythematous base 4.5 cm in diameter which reached its maximum intensity at the end of two hours.

An agglutination reaction carried out with the patient's serum was markedly positive with a serum dilution of 1:160 and was questionably positive at 1:320.

Although the patient was practically moribund for the first three weeks in the hospital, the temperature tended to be low grade, varying from normal to 101 F. The pulse rate fluctuated with the temperature from 80 to 130 per minute. The respiratory rate for the first three weeks usually varied between 30 and 60 per minute.

The patient was given ammonium chloride syrup of hydriodic acid and codeine. Iodide therapy was instituted with 15 grams of potassium iodide three times a day and, in addition, 5 grams of creosote daily. This treatment was supplemented a week later by the use of daily doses of 1½ grains (0.1 Gm.) of sodium iodide intramuscularly.

After three weeks of treatment, the patient began to show a marked and progressive improvement, which resulted in her discharge from the hospital six weeks after admission. She was seen by request four months after discharge, at which time she showed slight evidences of myocardial weakness that were attributed to the presence of a considerable degree of arteriosclerosis. An intensive search could bring forth no evidence of monilia infection. Sputum, blood, urine and stool examinations were negative. A slight cough and crepitant rales at both lung bases disappeared on digitalization and the patient again felt entirely well.

Intracutaneous administration one month after discharge of 0.1 cc of a nucleoprotein fraction of the monilia recovered from the sputum of patient 1 produced no reaction.

CASE 3—An American born housewife, aged 30, admitted to the Boston City Hospital Nov. 28, 1932, complained of pain in the right side of the chest. Five years before entry she was told that she had pulmonary tuberculosis and was sent to a sanatorium. The patient left that institution against advice about a year before her admission to the Boston City Hospital but promised to continue the therapy with her own physician. Two weeks before entry she began to experience sharp stabbing pains in the right side of the chest, associated with difficulty in respiration.

The family and marital history were not remarkable. A communication from the sanatorium stated that, before pneumothorax therapy (1930), a roentgenogram of the chest showed infiltration of the left lung field and cavity formation.

Density at the right apex was also noted. Sept 10, 1931, a roentgen study revealed a left pneumothorax with good collapse and infiltration of the right apex. The 1st sputum positive for *Bacillus tuberculosis* was obtained Oct 9 1930. The weight on discharge, in November 1931, was 127 pounds (57.6 Kg). The sputum was negative for acid-fast bacilli.

On admission to the Boston City Hospital, the patient was emaciated. The throat was moderately injected. The trachea was deviated to the right and the chest showed diminished expansion on the left. The right apex was dull to percussion, with increased breath sounds and increased whispered voice. No rales were heard. The left side of the chest exhibited flatness to percussion posteriorly below the level of the fifth rib. Breath sounds and rictile fremitus were markedly diminished over the area of flatness. The right cardiac border was found to be 2 cm outside the right sternal border. Examination of the abdomen revealed slight epigastric tenderness. The systolic blood pressure was 80 and the diastolic pressure 54. She weighed 116 pounds (52.6 Kg).

The urine varied in specific gravity from 1.012 to 1.015, with a slight to a large trace of albumin. The sediment centrifugated, showed occasional red cells, white cells and granular casts.

The hemoglobin was 70 per cent (Sahli). The white blood cells numbered 16,100 per cubic millimeter of blood with a differential count of polymorphonuclear neutrophils 70 per cent, lymphocytes 26 per cent, monocytes 4 per cent, and eosinophils 0 per cent. The Kahn test was negative.

Seven blood cultures were taken, five of which were negative; one showed *Streptococcus viridans* and one *Staphylococcus aureus*, obviously a contamination.

The sputum was seromucoid to purulent in character. Fifteen smears of the sputum were examined, one of which was positive for acid-fast bacilli and twelve showing large numbers of yeastlike organisms. On three occasions the sputum was carefully collected for culture and all specimens showed the fungus.

A roentgenogram of the chest on entry showed a left pneumothorax with no free fluid and an infiltration of the right infraclavicular region. The latter was thought to be due to tuberculosis. Roentgenologic studies made a few days later revealed the presence of free fluid in the left side of the chest.

Agglutination reactions carried out with the patient's serum and the organism isolated from the sputum showed a positive reaction with a 1:80 dilution of the serum and a questionable reaction at 1:160.

The patient remained in the hospital one month, showing essentially no change for the first three weeks. The temperature showed a diurnal fluctuation although not always with an afternoon peak. It frequently rose to 102 F as the maximum and often dropped as low as 98 F. The respiratory rate during the first three weeks varied from 15 to 30 and the pulse rate fluctuated markedly with the temperature from 88 to 128.

The cough was controlled with elixir of terpin hydrate and codeine. The addition of a chest swathe with complete rest in bed and pneumothorax therapy afforded marked relief for the pain in the chest.

As the patient began to improve symptomatically, she showed a marked disinclination to remain in the hospital for continued therapy and was discharged against advice at the end of the fourth week in the hospital. During this last week, the temperature varied from 98.6 to 99 F, the pulse rate was between 80 and 90 and the respiratory rate was 20. She coughed slightly and had slight pains in the chest. There were still signs of fluid in the left side of the chest and the sputum showed large numbers of yeastlike organisms with no acid-fast bacilli.

MICROLOGY

The organisms in the sputums in all the cases of this report were identified first in routine stained smears for *Bacillus tuberculosis* in which they were observed as numerous clumps of single and budding cells and mycelia stained by the methylene blue counterstain. Subsequently they were demonstrated as deep violet staining organisms when stained by the method of Gram. In each instance specimens for culture were collected only after the most superficial organisms had

been removed from the mouth by several rinsings with saline solution, after which a deep cough usually furnished abundant material for examination. Cultures of three specimens of sputum were made in each case on Sabouraud's maltose agar. The most abundant growth was obtained by streaking the characteristic white flakes in the sputum on plates and incubating at 37.5 C for four days, at the end of which time numerous round, somewhat conical, ivory white colonies, from 0.3 to 0.5 cm in diameter, were found.

The classification of each organism was based on studies of cell morphology, mycelia and ascospore production, cultural characteristics, sugar fermentations and virulence for animals. The organisms from all three cases were identical.

Cell Morphology—Hanging drop preparations of cultures from Sabouraud's slants and in plain bouillon were utilized in these studies. After forty-eight hours' incubation at 37.5 C, the fungus appeared, chiefly as single cells and budding forms with a few short thick hyphae. The cells measured from 4 to 12 microns in diameter and buds varied from a fraction of this to the same size as the parent. Hyphae showed marked variation in length and were from 15 to 20 microns in thickness. After longer periods of incubation, the hyphae increased markedly in number and in length and showed definite segmentation with oval conidia, from 2 to 5 microns in greatest diameter.

Mycelia Production—Isolated colonies on Sabouraud's maltose agar plates at the end of six days' incubation at 37.5 C showed a narrow fringe of mycelia. This widened to a band from 0.5 to 1.0 cm in width on about the fifteenth day of incubation, at which time the colonies had become brown and dry, and growth had ceased. Gelatin stabs were made and incubated at room temperature for seven days, at which time a marked lateral outgrowth appeared along the line of stab, greatest in extent at the surface and gradually decreasing to less than 1 mm in width in the depths of the tube, thus growing in the typical inverted "pine tree" arrangement. No liquefaction occurred. Microscopic studies of the mycelia were made by fixing the gelatin stab culture in 10 per cent neutral solution of formaldehyde for twenty-four hours, cutting it in thin slices and mounting it on slides in glycerin jelly. The mycelial threads began in a mass of cells in the line of the stab and extended outward with clusters of from ten to twenty conidiophores arranged at intervals of 30 microns or less along the thread. The largest clusters were found in the distal portions and an occasional segmented branch arose from the clusters and extended outward for from 150 to 200 microns, with a few round or oval conidia arranged at the points of segmentation and terminally.

Ascospore Production—The surface growth on gelatin stabs was examined after seven days' incubation for the presence of ascospores.²⁵ In no instance could any be demonstrated.

Cultural Characteristics—The colonies on Sabouraud's agar at the end of four days' incubation at 37.5 C were as described in cultures of the sputums. In plain bouillon, growth was abundant in the bottom of the tube with clear fluid above. No ring or pellicle was formed.

Sugar Fermentations—A base was used, consisting of 1 per cent peptone and 0.5 per cent sodium chloride,

²⁵ See R. N. Zerkas, L. G. and Cornwell, M. A. The Presence and Importance of Yeastlike Fungi in the Gastrointestinal Tract in Pernicious Anemia in Other Diseases and in Normal Individuals. *Am J M S* 175: 153-174 (Feb) 1928.

with 1 per cent Andrade's indicator added and so adjusted as to be light pink when hot and colorless when cold. This was autoclaved for twenty minutes at 15 pounds pressure. To each tube, 1 per cent of chemically pure sugar was added the latter having been sterilized in 10 per cent solution previously, by heating in the Arnold steam sterilizer for twenty minutes on each of three successive days. Control tubes consisted of the peptone water base inoculated with the fungus. Dextrose, levulose, maltose, saccharose, galactose, lactose, mannose, rhamnose and raffinose were used in the determinations. Inoculants were made from the growth on plain agar slants after forty-eight hours' incubation at 37.5 C. Gas formation was shown by the use of Durham tubes. Readings were made at the end of two, three, five and seven days' incubation at 37.5 C. These were the same on the fifth and seventh days, and this was accepted as the characteristic fermentation. Results were as follows with organisms from each of the three cases: acid and gas production in dextrose, levulose, mannose and maltose, acid in saccharose and galactose, no acid or gas in lactose, raffinose and rhamnose.

Milk—A special milk medium containing 0.5 per cent calcium lactate was prepared, according to the method described by Stovall and Bubolz.²⁶ This was inoculated with 0.1 cc of a salt solution suspension, obtained by washing a forty-eight hour growth from a Sabouraud agar slant. The cultures were incubated at 37.5 C for one week. No coagulation was observed.

Virulence—Virulence tests were carried out, rabbits being used. Approximately 100×10^6 organisms were injected into an ear vein. Each of the three fungi caused death in from four to six days. Autopsy revealed numerous small abscesses in the kidneys, from which cultures yielded organisms identical with those injected. Blood cultures were negative. Microscopic studies confirmed the gross diagnosis and yeastlike fungi, occurring chiefly as single and budding forms, but with a few hyphae, were demonstrated in the lesions. Intrapulmonary injection of 50×10^6 organisms in 1 cc of saline solution was made. One rabbit injected with the organism from patient 2 died in six days with macroscopic lesions in the kidneys as already described, and with nodules at the point of injection in the lung and fibrin deposit on the pleural surface. Microscopic studies showed kidney lesions as described previously. Sections through the nodules in the lungs showed extensive necrosis of the parenchyma, collections of polymorphonuclear neutrophils and numerous yeastlike organisms with short thick hyphae. The other rabbits were killed six weeks after injection and presented marked adhesions between the pleural surfaces in the region of injection and nodules from 0.3 to 0.5 cm in diameter with soft yellow centers in the adjacent lung tissue. Cultures yielded the same organisms as described previously. Microscopic examination showed these lesions to consist of a central necrotic zone, containing numerous single and budding cells and masses of mycelia, surrounded by a zone of connective tissue.

Organisms from the sputums of each case (1) were yeastlike in structure, (2) produced segmented mycelia readily in culture mediums, (3) did not form ascospores, (4) fermented certain sugars with gas as well as acid formation, (5) did not coagulate milk, and (6) were pathogenic for rabbits. On the basis of the first four of these characteristics, the organisms are identified as belonging to the genus *Monilia* or *Parasaccharomyces*.

Because of the pathogenicity for rabbits, as well as the sugar fermentations, all three fungi can be placed in the group *Parasaccharomyces* A, described by Nye.² Except for the fact that no gas formation was observed in galactose these organisms might be positively identified as *Monilia* type II, recently described by Stovall and Bubolz,²⁰ which includes, among other species *Monilia albicans* Craik, *Monilia psilosis* Ashford and *Monilia pinovi* Castellani. Since the most characteristic biochemical reactions are obtained in maltose and saccharose the organisms from these three cases would seem to belong to *Monilia* type II, in spite of their failure to form gas in galactose.

COMMENT

Three cases of pulmonary moniliasis have been presented, in two of which the yeastlike fungus was the primary etiologic agent and in one a secondary invader. The clinical pictures varied markedly and it can be readily seen that symptoms and physical signs alone cannot be used as dependable criteria in the diagnosis of the disease. The establishment of the diagnosis of pulmonary moniliasis requires certain definite evidence in addition to a suitable clinical picture. The presence of typical organisms in the absence of acid-fast bacilli, in a carefully obtained specimen of the sputum is of utmost importance.²⁷ Although it has been maintained that these organisms can be found in the sputums of normal individuals,²⁸ most observers feel that monilia is an unusual mouth organism.²⁹ Consequently, its presence in any sputum deserves careful consideration.

It has also been maintained that an absolute diagnosis of pulmonary moniliasis depends on the demonstration of the pathogenicity of the isolated organism for laboratory animals.³⁰ Against this point of view, however, it has been shown that moniliasis causing similar bronchial reactions may vary greatly as regards their pathogenicity.³¹ The fact that yeastlike fungi may be pathogenic for man and not for laboratory animals has been a repeated observation.³² Also, moniliasis that are fairly common inhabitants of the normal gastro-intestinal tract in man have been found by Nye³¹ to cause death in rabbits when administered intravenously. Peckham³³ has shown that monilia, saprophytic in the human being in other locations is pathogenic for guinea-pigs. Hence it would seem that the animal pathogenicity of this group of fungi is no criterion for proof of etiologic relationship to disease in man. Many investigators have come to the conclusion that the mere presence of *Monilia* in large numbers in the sputum of a patient suffering from bronchopulmonary disease indicates that these organisms are primary etiologic agents or secondary invaders.³⁴

Although much has been written concerning the value of complement fixations and agglutination reactions these observations have not been consistent enough to be of sufficient value to establish the diagnosis.³⁵

Agglutination reactions with monilia strains from the cases reported in this paper and twenty-six serums from patients with no evidence of monilia infection showed negative results in only nine instances. The other serums showed agglutinin titers ranging from 1:5 to 1:80 only one, however, showing this rather high value. Skin tests have been more valuable. Balog and Grossi³⁵ report nonspecific reactions with killed monilia cultures, but accurate specific reactions with living organisms of the species *Monilia pinoyi*. The results with the intradermal injection of killed cultures recorded here agree with theirs. Living cultures of *Monilia pinoyi* were not utilized. The results with a monilia nucleoprotein fraction, prepared by Dr R. N. Nye and so diluted as to give negative reactions when administered intracutaneously to thirteen controls, showed a specific reaction in case 1 after vaccine therapy but was negative in case 2 one month after discharge from the hospital. One control subsequently showed a positive reaction.

So, at present, it seems necessary to base a positive diagnosis of primary monilia infection on the presence of large numbers of the organism in the sputum in the absence of *Bacillus tuberculosis* and with additional evidence that may be obtained from roentgenologic observations, therapeutic tests with iodides and, possibly, skin tests performed with living organisms of the species *Monilia pinoyi*. The possibility of inducing infection of the skin by use of the latter organism would seem to be a factor that would make this test undesirable. Balog and Grossi, however, with the strain used by them, in no instance observed such a result. Perhaps further studies with a nucleoprotein fraction from monilia may give as good a result and yet offer a less dangerous means of demonstrating the relationship existing between the isolated yeastlike organism and the lesion in the patient.

It is important to bear in mind that no characteristic clinical picture is found in pulmonary infections with *Monilia*. Although most cases may have a striking similarity to pulmonary tuberculosis, it is not unusual to find cases of pulmonary moniliasis with an acute onset. The diagnosis of moniliasis should be borne in mind in any case of pulmonary disease in which the etiology is questionable.

SUMMARY

In three cases of monilia infection of the lungs, the organism was the primary agent in two and in one an invader secondary to *Bacillus tuberculosis*.

A marked variation in the clinical picture of pulmonary moniliasis was observed in the cases presented.

Excellent results were obtained with the use of iodides and with iodides supplemented by vaccine in the treatment of the cases of primary infection.

There are means of demonstrating the relationship of *Monilia* recovered from the sputum to the disease process in the patient. Agglutination reactions proved to be of uncertain value in the establishment of a diagnosis.

It is important to consider a diagnosis of pulmonary moniliasis in cases of unproved and atypical tuberculosis.

It is suggested that, in the wide group of cases clinically classified as chronic bronchitis, *Monilia* should be considered as one of the many possible etiologic agents.

NEUTROPENIA FOLLOWING AMIDOPYRINE

PRELIMINARY REPORT

ARTHUR M. HOFFMAN, MD

E. M. BUTT, MD

Assistant Clinical Professor of Medicine and Assistant Professor of Pathology, respectively, University of Southern California School of Medicine

AND

N. G. HICKEY, MD

LOS ANGELES

The increasing number of cases reported in recent years presenting the syndrome of agranulocytic angina or malignant neutropenia has excited comment from many observers. Numerous drugs, organisms and toxins have been connected with the disease entity but definite confirmatory clinical and experimental data have been lacking.

Kracke¹ in 1932 was able to induce the characteristic blood picture in rabbits with small subcutaneous injections of benzene following the lead of Selling² in 1916 in demonstrating the leukotoxic effects of benzene on myeloblastic tissues. Kracke also produced a marked leukopenia with subcutaneous injections of ortho-oxybenzoic acid and by the intravenous injections of hydroquinone. He was unsuccessful in depressing the leukocyte count with a group of other substances, as acetphenatidin, peralga (barbituric acid and amidopyrine), dial, resorcinol, pyrocatechin, orthocresol, para and meta-oxybenzoic acid and 50 per cent alcohol. To one rabbit he administered from 5 to 10 grains (0.3 to 0.65 Gm.) of amidopyrine daily by mouth for forty-five days. A persistent leukocytosis was obtained.

During the past six to eight years, one of us (A. M. H.) has had occasion to treat fourteen consecutive cases of agranulocytic angina. Thirteen of the patients died—some before the advent of pentnucleotide therapy and several since. In August 1933 one patient developed the clinical picture after two weeks' ingestion of dinitrophenol, which she took on her own behest for reduction purposes. Following roentgen therapy and the administration of pentnucleotide, she recovered. Her illness prompted us to review all the preceding cases of agranulocytic angina we had observed and, to our astonishment, we noted that the only common factor in the twelve cases seen to that date had been the ingestion of amidopyrine. All of these patients had received amidopyrine alone or in conjunction with codeine for the pain of arthritis, sciatica, bone tumor, and so on. A few had received some barbitol products, as phenobarbital, pentobarbital or iso-amylethyl barbituric acid. None had been given allylisopropylbarbituric acid combined with amidopyrine (allonal).

We therefore determined to investigate the possibility of the experimental production of the neutropenic state by means of amidopyrine.

Oct. 27, 1933, Madison and Squier³ reported before the Central Society for Clinical Research their experiences concerning thirteen cases of agranulocytic angina,

From the University of Southern California School of Medicine and the Santa Fe Coast Lines Hospital.

in all of which various barbiturates, usually in combination with amidopyrine, had been administered. They gave allylisopropylbarbituric acid with amidopyrine (allonal) to eleven rabbits. One rabbit showed an abrupt drop in the granulocyte count on the twenty-sixth day and died on the thirtieth day. There was no effect on the remaining rabbits.

In November 1933, Watkins⁴ commented on the possible role of barbiturates and amidopyrine in the causation of leukopenic states in a series of thirty-two cases seen at the Mayo Clinic. Of this group of patients, "twenty-four had taken amidopyrine or a derivative of barbituric acid for varying periods before the onset of the granulocytopenia." In the remaining eight cases no record could be found that any drug had been used before the onset of the illness, but all had been under medical observation for chronic complaints or had been hospitalized for surgical procedures. It is possible that these patients may have received barbiturates or amidopyrine."

Subsequent to the publication of these observations, from personal communications at least four other patients have been noted to develop malignant neutropenia following the use of amidopyrine.

Under our very eyes, our fourteenth patient recently developed the disease.

A man, aged 58, was admitted to the Santa Fe Hospital for an otitis media, Nov. 27, 1933. The temperature was normal. The white blood corpuscles numbered 6000, with 58 per cent polymorphonuclear leukocytes. A suppurating mastoid developed, and on December 18 a mastoidectomy was done. During the following thirty-six days he received a total of 75 grams (4.9 Gm.) of amidopyrine for headache. Jan. 23, 1934 he developed a sore throat and temperature to 103.4. His leukocyte count on that day was 1,500, with 3 per cent polymorphonuclear cells. He died January 27, in spite of vigorous therapy with penicillins and liver extract. His leukocytes dropped to 450 cells with an entire absence of neutrophils, before death.

The remainder of our cases practically duplicate this. All but one of the patients had received amidopyrine in doses of from 5 to 25 grams (0.3 to 1.6 Gm.) a day—often in association with half grain (0.03 Gm.) doses of codeine for relief of pain of varied origin. One patient had two attacks six months apart, dying in the second. In the one exception in our series of fourteen cases, only dinitrophenol, 100 mg. four times a day for two weeks, was administered. The patient did not take any other medication whatever and is certain that no amidopyrine or barbiturates were available in her home. She is the only patient in the series who is alive.

Commencing in December 1933, our experimental work on rabbits was carried on. Amidopyrine alone was used in contrast to the combination of Madison and Squier of amidopyrine with allylisopropylbarbituric acid, because amidopyrine was the only drug used in thirteen of the fourteen cases we had observed.

The results of our animal experiments will be given in detail in a later report. At the present time we have definitely shown that amidopyrine has an effect on the hematopoietic system of rabbits. Doses of this drug varying from 0.2 to 0.9 Gm. per kilogram given by mouth produce a definite leukocytosis followed in a few weeks by a depression of the total white count. In some of the rabbits the proportion of polymorphonuclear leukocytes has been reduced to as low as 8 per cent, while in all the rabbits the granulocytes have been

below 20 per cent during the depression of the total counts. The controls remained unchanged.

COMMENT

The common factor in amidopyrine, dinitrophenol, benzene, arsphenamine, ortho-oxybenzoic acid and hydroquinone, all of which have produced neutropenia experimentally or clinically, is the benzene ring. Whether the latter is the actual toxic agent in the production of neutropenia needs further experimentation, part of which we are now undertaking. Our work points to amidopyrine as having a definite effect on myeloblastic tissue similar in man and in rabbit. Whether this is an individual susceptibility of the nature of an allergic reaction, as suggested by Pepper,⁵ remains to be determined. Until it is, the use certainly of amidopyrine alone or in combination with other drugs should be restricted to patients having leukocyte counts several times a week.

1136 West Sixth Street

TUBERCULOUS CERVICAL ADENITIS

A STUDY OF POSTOPERATIVE END RESULTS

E. MACD. STANTON, MD

AND

GOMER RICHARDS, MD

SCHENECTADY, N. Y.

The data presented in this paper are based on a series of 115 cases of tuberculosis of the cervical lymph nodes in which operations were performed by one of us (Stanton) over a period of twenty-six years. One hundred and seven of these cases have been followed for a total of 1,348 years, or an average of 12.5 years each. In all but two or three perfectly typical cases, the diagnosis was confirmed by histologic examination of tissues removed at operation.

This group consisted of 56 males and 59 females. The age distribution when these cases came under our observation is given in table 1.

The duration of the glandular involvement before surgical intervention was sought is given in ninety-four histories. Forty-five or 48 per cent, came to operation within six months after the enlarged glands were first noted, nineteen, or 22 per cent, between six months and a year, eleven during the second year, nine during the third year, and ten after more than three years.

The previous treatment as recorded in the histories is given in table 2.

When these patients came under our observation, they presented pathologic lesions varying from multiple involvement of the great majority of nodes on one or both sides of the neck to involvement of only a few nodes or involvement of one or more caseous nodes associated with localized abscesses. Of the 115 cases 41 were described before operation as presenting abscesses or fluctuating masses in the neck. In twelve additional cases there were sinuses. Thus the abscess and sinus cases comprised nearly half the total cases. Eight patients—all adults—presented at the time of their first visit definite clinical evidences of pulmonary tuberculosis.

The treatment given these patients while under our observation was almost entirely surgical and hygienic. X-rays, radium, special lights and vaccines were

scarcely used at all. The same may be said of the various local injections such as Beck's paste.

The surgical treatment in the cases covered by this study varied according to the type of lesion from complete excisions involving entire chains of glands to the

TABLE 1—Age of Patients When They Came Under Observation

simple incision of localized abscesses with the simultaneous removal of the node or nodes responsible for the abscess. The importance of removing the causative node is illustrated by the fact that in this series there were thirteen cases in which abscesses had been previously drained without removal of the gland and all of them had continued to drain constantly or intermittently until the causative focus was removed, after which they promptly healed.

The time required for healing, the duration of drainage and sinus formation were noted in fifty-eight of the histories. For the most part, healing was by primary intention except at drainage sites. Prolonged drainage is noted in a number of cases. Two patients said that it took two months, three said that it required four months. Drainage continued for three months in

TABLE 2—Previous Treatment

one case, about one year in five cases and for three years in one case. This patient had become pregnant shortly after operation and this was considered a factor in continuing the drainage. Two patients in whom healing had been good subsequently had a secondary breaking down of tissue with sinus formation when they became pregnant. Both of these pregnancies were within a year of operation.

Postoperative care was largely directed along hygienic lines, including fresh air, rest and diet. Most of the patients returned to their usual occupations as soon as their incisions were healed. Therapeutic injections of tuberculin were used postoperatively in only one case. No patient was given roentgen or radium treatments postoperatively although one patient subsequently had roentgen treatments for a recurrence.

At the end of one year following the date when these patients came under our observation approximately 73 per cent had apparently recovered and were described as being in excellent or good health. Eight are known to have pulmonary tuberculosis as shown on admission and approximately 20 per cent still present evidences of nonpulmonary tuberculous infection

in the form of sinuses or demonstrable glandular enlargements in some part of the body. In the course of time all of the patients without pulmonary involvement not yet cured at the end of the first year have recovered as far as any evidence of active tuberculosis was concerned at the time when they were last observed.

At the end of the first year, six patients presented complaints directly referable to the operation itself. The complications may be listed as in table 3.

All of these minor complications cleared up in the course of time.

The data as to the period elapsing before operation the repeated operations and long-continued treatment in some cases, and the fact that one year after radical surgical treatment between 20 and 30 per cent of the patients still had symptoms relative to the disease is simply in line with the well known chronicity of tuberculosis.

It is only when these cases are followed for relatively long periods that the remarkably good ultimate prognosis of this disease becomes apparent.

TABLE 3—Complications in Six Operative Cases

Tension distress in shoulder	1
Drooping shoulder with difficulty in raising arm to level of opposite shoulder	1
Numbness on side of face	1
Increased sensitivity on side of face	1
Face crooked since operation (partial involvement of inframaxillary branch of facial nerve)	1

Of the 103 patients traced for periods longer than one year and averaging thirteen years each, none had died of a nontuberculous disease and only four have died of pulmonary tuberculosis.

Among the ninety-nine survivors, at the time of their last examination only one presented a small but definite tuberculous gland in the neck. In the remaining ninety-eight, all evidences of active tuberculosis have disappeared.

During the time these patients have been under observation, their nontuberculous morbidities have been about what might be expected for a similar age group over a like period of time. Among the observations noted in the histories may be listed the conditions presented in table 4.

TABLE 4—Complications Noted in the Histories

Bilateral encephalomyelitis and hysterectomy for atrophy plus one urinary frequency	1

Only four of the 107 traced patients have subsequently died of pulmonary tuberculosis. These deaths all occurred in adults who were known to have some degree of active pulmonary tuberculosis at the time they were operated on. The shortest duration was one year and two months and the longest ten years and four months after operation. The other two lived two

years and three months and four years, respectively. Two were men and two were women. The ages at the time of operation were 22, 27, 35 and 19 years and at the time of death 23, 31, 37 and 29 years, respectively. Four other patients with active pulmonary tuberculosis at the time of operation were aged 22, 23, 23 and 43 years, respectively. One was lost track of within the first year but the other three have been followed twelve, sixteen and twenty-one years, respectively. They all report in excellent health at the present time. One child, aged 2 years at the time of operation, was sent to a tuberculosis camp for a while but now, fourteen years later, is in excellent health. It is of interest to note that this boy is a son of one of the adults who died of pulmonary tuberculosis.

During the period these cases have been under observation, the general mortality rate for tuberculosis in this and other countries has been changing so rapidly that it is impossible to calculate the expected mortality from pulmonary tuberculosis for a similar sex and age group without lymph gland tuberculosis. However, in the group under observation, not one of the ninety-nine patients who came for treatment of tuberculous cervical lymph nodes without demonstrable active pulmonary tuberculosis has ever developed any serious form of pulmonary tuberculosis during the aggregate of 1,279 years they have been under observation.

Such observations seem to point definitely to the conclusions:

First, tuberculous cervical adenitis occurring in children and young adolescents when properly treated does not subject these individuals to a more than usual subsequent death rate from pulmonary tuberculosis.

Second, it is difficult to escape the conclusion that lymph node tuberculosis occurring in early life is a clinically observable phase of a form of tuberculosis that serves as an immunizing process, actually protecting the individual against lethal forms of tuberculosis.

We feel that the series of cases analyzed in this study is large enough numerically and that the follow-up period has been sufficiently long so that in all probability the concept regarding the prognosis of this disease as herein presented is correct for the period under consideration.

We can find no similar end result reports covering a period of high tuberculosis mortality such as the late nineties or early years of this century. Certainly our results have been much more favorable than those reported by most surgeons and especially those of a slightly earlier period.

Raymond Pearl and others have shown that the enormous drop in the death rate from tuberculosis that has occurred in recent years is a world-wide phenomenon but doubtfully influenced by local or even country-wide crusades against the disease.

Twenty-five years ago lymph gland tuberculosis was a common disease seen frequently in all communities. Today it is a rare disease encountered only occasionally in even the largest clinics. It is just possible that the highly favorable prognosis as shown in our series may be in part at least the result of some great biologic phenomenon associated with this disease little understood at this time. It is quite certain, however, that no facts observed in association with this series can be interpreted as an indication that lymph gland tuberculosis occurring in children or young adults is particularly liable to develop later into pulmonary or other serious forms of tuberculosis.

ALLERGIC-LIKE REACTIONS FROM SODIUM MORRHUATE

IN OBLITERATION OF VARICOSE VEINS

LEO M. ZIMMERMAN, MD

CHICAGO

The search for a perfect sclerosing agent for the obliteration of varicose veins has been marked by the adoption and subsequent neglect of one solution after another. The requirements for an ideal solution are that it be effective, safe and painless. These requirements have largely been fulfilled by sodium morrhuate, and this preparation has been widely accepted as the closest available approach to the ideal medium. Its freedom from danger of local and general reaction has been particularly emphasized. My experience with sodium morrhuate, like that of many others, has been extremely satisfactory, and in both private and clinic work it has largely supplanted all the other agents used. In the absence of any fear of general reaction, I have not hesitated to use it and to advocate it freely. Several recent experiences, however, have indicated that sodium morrhuate may give rise to allergic reactions in sensitized persons. I am unable to find any mention of this possibility in the literature, and it is my purpose in this communication to call attention to it in order that adequate measures may be taken to avoid it.

REPORT OF CASES

CASE 1—Mrs. J. N., aged 49, with a negative allergic history, had had sphenous vein ligation followed by a series of sodium morrhuate injections at intervals of from one to two weeks, with no systemic reaction of any type. When the veins were almost entirely obliterated, an interval of seven weeks was permitted to elapse between treatments, following which two injections of 1 cc each were given. About twenty minutes after the second injection the patient complained of extreme weakness and dizziness. Consciousness was retained and there was no cough, pain in the chest, or expectoration. The expression was anxious but there was no cyanosis. There was no detectable pulsation of the radial or other arteries and auscultation revealed an absence of heart tones over the precordium. The head of the table on which the patient was lying was lowered and 1 cc of epinephrine was administered hypodermically. After several minutes the patient stated that she felt better but she was still pulseless, and the systolic blood pressure was found to be 70. When ephedrine was given the blood pressure gradually returned toward normal, and the patient was permitted to go home. On the following day she seemed completely recovered.

Dr. S. M. Feinberg saw the patient during the attack and termed it an anaphylactoid reaction. He subsequently made skin tests for sensitization to sodium morrhuate. The scratch test was negative but a positive reaction was obtained on intradermal injection. The patient apparently was not sensitive to sodium morrhuate when the treatments were begun. She became sensitized, however, during the course of treatment, and an injection after an interval resulted in a severe reaction, which resembled an anaphylactic shock.

CASE 2—Mrs. M. G., aged 36, with a negative allergic history, received an initial injection of 0.5 cc of sodium morrhuate. One week later two injections of 1 cc each were given. On the following day a severely itching eruption appeared on the neck and chest. She then recalled a milder irritation of the skin of the chest following the first injection. Examination revealed an intense dermatitis involving the chest, neck, face and arms. A dermatologist consulted by the patient considered the lesion a toxic erythema of a papular and urticarial type and thought it might well be allergic in origin. Intradermal skin tests were again positive.

From the Peripheral Circulatory Clinic of the Department of Surgery, Northwestern University Medical School.

CASE 3—Mrs H F had a previous history of urticaria, for which sensitization tests were being made. She had received a number of dextrose and salt injections in the varicose vein clinic of the department of surgery of Northwestern University Medical School with no untoward effect. Following her initial injection with 4 cc of sodium morrhuate, however, a severe systemic reaction occurred. It began about fifteen minutes after the injection and was characterized by faintness, weakness and rapidity of the pulse and repeated vomiting. The symptoms lasted for over an hour and then gradually disappeared.

CASE 4—Miss I B had a severe urticarial reaction following the initial injection with sodium morrhuate.

COMMENT

The last three patients mentioned were apparently sensitive to sodium morrhuate and developed reactions following the initial injections. The first patient had received numerous injections, during the course of which apparently, sensitization appeared. That such reactions are not uncommon is evidenced by the fact that other clinicians with whom I have spoken have had similar experiences. I am indebted to Dr Geza de Takats for the following statement regarding his material:

I have observed to date seven cases of sensitization to sodium morrhuate, occurring during the injection treatment of varicose veins. In the first patient, from three to four injections of sodium morrhuate were given at weekly intervals. Following the third treatment, large blotches of urticaria developed around all the sites of previous injection, followed by a generalized itching and rash. In the second patient, treatment was given every third or fourth day, but she missed one treatment, permitting a week to elapse between injections. Following the last treatment, an enormous edema and rash of the entire extremity appeared, with high temperature and a white count of 17,000 with 35 per cent eosinophils. A generalized, confluent rash completed the picture. The third patient behaved very similarly to the first. The fourth patient was remarkable in that she only received one injection after which an extensive rash on both lower extremities developed. The fifth patient was known to have had hay fever. The sixth patient also showed an unusual picture. She had had biweekly injections for three weeks. Three weeks after the last treatment she developed localized, badly itching patches at all sites of previous injections. She had eaten fish the night before which was the only sensitizing factor she could think of. The seventh patient, a woman with very thin transparent skin and red hair developed a very severe weeping eczema over both lower extremities following weekly injections of sodium morrhuate.

In none of these patients was there an immediate anaphylactic shock. Scratch tests made *after* the allergic reactions had subsided were usually negative. Whether a scratch test during treatment would be of any help is now being determined. Of interest is an eighth case in which 5 per cent potassium oleate was used and very severe eruptions observed. There is no morrhuate acid at all in this preparation nor is this oil aromatic.

The source of the allergic reaction to sodium morrhuate is questionable. Sodium morrhuate is an aqueous solution of saponified cod liver oil. Whether the saponified fatty acids themselves are capable of producing an allergic type of reaction or whether it is due to an admixture with liver proteins is as yet unknown. A third possible explanation is that the hemolysis from contact of the patient's blood with the solution may result in the liberation of protein substances that are responsible for the reaction. An experimental answer to this problem is being sought.

It will be seen from the reported cases that scratch tests for sensitization to sodium morrhuate have been uniformly negative. Intradermal injections on the other hand gave positive reactions in several of the patients who exhibited sensitization phenomena. Unfortunately, similarly positive results were obtained

on intradermal injection in some normal controls, and the possibility of a nonspecific irritative reaction is difficult to rule out. To minimize the dangers of sensitization reactions, it is my practice never to exceed an initial dose of 0.5 cc of the solution. In patients in whom an interval has elapsed between injections, during which sensitization may have developed, I make a preliminary intradermal injection. If no local reaction occurs, the intravenous treatment is resumed. If a positive reaction develops, the further use of sodium morrhuate is discontinued and another sclerosing agent employed in its stead. Since these precautions were initiated, no further reactions have been observed.

SUMMARY

Sodium morrhuate has been widely accepted as the solution of choice for the obliteration of varicose veins. My experience in general has been extremely favorable. In certain cases, however, sensitization to the solution may exist or may develop. In two of the reported cases this sensitization manifested itself in a severe general shocklike reaction. In two others, skin manifestations occurred. It is urged that the possibility of such a reaction be kept in mind, just as in all other intravenous injections of possibly allergic substances, and that, particularly in patients who have received morrhuate injections followed by a rest period of several weeks or more, intracutaneous skin tests be made to preclude the danger of a serious anaphylactic response.

TRICHINOSIS OF MAN A COMMON INFECTION

WILLIAM A. RILEY, PH D

AND

CHARLES H. SCHEIFLEY, B A

MINNEAPOLIS

For years past the senior author has stated to his students in parasitology that trichinosis in man was very far from being a rare disease in the United States. This statement was based on the number of serious cases that come to the attention of medical men and parasitologists, and on the well known fact that diagnosis of typhoid, rheumatism and malaria is not infrequently made when the symptoms are actually due to the presence of trichinae.

In order to obtain more definite data relative to the incidence of trichinosis, a project was outlined involving the examination of diaphragm muscles from the cadavers used in the dissecting rooms of the University of Minnesota Medical School, similar examination of autopsies representing a more normal population, and extension of earlier studies on the occurrence of the encysted worms in local hogs, rats and other animals. Only during the past year through the active participation of the junior author, have studies on the first sub-project been feasible. The results obtained are so strikingly out of line with current conceptions that they should be brought to the attention of the medical profession.

For his ready cooperation in making material available for this study we are under obligation to Dr C M Jackson head of the Institute of Anatomy. Assistance was rendered also by Dr R O Christenson and Miss Mildred King.

From the University of Minnesota

More than a century ago the calcified cysts of trichina worms were noted, in the dissecting rooms of Europe, as gritty particles which turned the edges of scalpels. Nevertheless, data regarding their presence in the human body are surprisingly meager and those on record are of but little value. The cysts are invisible to the naked eye unless they are calcified and even then they would be overlooked unless present in enormous numbers. For this reason they would be overlooked altogether in routine postmortems. Ransom¹ considering "only those series of autopsies in which it appears that trichinae were looked for in at least some of the autopsies" presents the accompanying tabular statement for the United States:

The figures given by the last two workers have been completely disregarded in the past, on the natural basis that they were chance observations in series too small to be of any significance. Those of Williams² have been accorded more weight but have often been discounted on the ground that the subjects were largely institutional.

Our own examinations of 117 carcasses in the anatomic laboratories of the University of Minnesota at Minneapolis revealed twenty cases of trichinosis, in

Infestation with Trichinae in the United States

subjects who were never recorded as exhibiting any symptoms of the infection. This makes for the group an incidence of 17.9 per cent. One series of fifty showed ten positives or 20 per cent. Only two workers since Ransom's report have noted anything comparable to our results and hence we have not brought his tabulation down to date.

Koen³ says "Dr. T. B. Pate of Washington University, St. Louis, has been conducting rather extensive research of trichina during the past years. His findings are almost sensational in that they indicate a prevalence of trichinosis in this section of approximately 10 per cent, which is far greater than is reported elsewhere." He had overlooked as had we, the fact that Dr. F. B. Queen⁴ had reported at the New Orleans meeting of the American Society of Parasitologists on 344 consecutive necropsies in Rochester, N. Y., in which artificial digestion of approximately 50 Gm. portions of muscle revealed fifty-nine, or 7.5 per cent, positives. In another series of fifty-nine diaphragms from necropsies in Boston, sixteen, or 27.6 per cent, were positive. The total of seventy-five positives out of 402 examinations gives a percentage of 18.6.

Our series from autopsies is as yet too limited to be significant. However, there is little reason to suppose that the group which reached the dissecting room would

have been exposed to trichina infestation any more than would the average of the population. The habit of eating imperfectly cooked pork is not one peculiar to any social stratum. Neither is the quality of the eating place one that insures safety. On the other hand it is probable that by the artificial digestion of muscle samples as large as those used by Dr. Queen we would have obtained a considerably larger number of positives. Our specimens were sliced thin and mounted in the trichina compressors of the general type of those used by the federal Bureau of Animal Industry during the period when microscopic inspection of pork was carried out.

A rough classification on the basis of severity of the infestation was made. Using on the average 5 square centimeters of the compressed muscle to a slide we classed those cases in which less than ten cysts were found as "light," from ten to fifty cysts as "moderate" and over fifty to a slide as "severe." The classification is not intended as an index of clinical symptoms, although it is certain that there must have been very definite illness in the half dozen cases classed as "severe." In no instance was there any information to indicate that there had been any suspicion of trichinosis. The most heavy infestation, exhibiting some 350 cysts to the slide, was that of an Irishman, 86 years of age who died of arteriosclerosis. The cysts were heavily calcified.

That light infestations should be overlooked during the lifetime of the host is to be expected. On the other hand, the fact that serious and even fatal cases not infrequently escape diagnosis was well illustrated during the 1924-1925 outbreaks of typhoid due to eating raw contaminated oysters. In attempting to trace the sources of all reported typhoid cases, the city health department of Boston discovered some twenty cases of active trichinosis, which had been diagnosed and reported as typhoid. Similar results were obtained in Chicago and doubtless, in other cities. Under usual conditions all of these cases would have remained charged against typhoid.

Two serious fallacies tending to an underestimation of the danger from eating imperfectly cooked pork persist and are widespread. The first is that government inspected meat is free from trichinae. As a matter of fact microscopic examination of pork for trichinae was discontinued in 1907. Since then no attempt has been made to carry on such examinations of pork in any part of the United States.

A second fallacy is the peculiar idea that, since federal examinations of millions of hogs showed a trichina incidence of only about 2 per cent, the danger of infection is slight. It would seem unnecessary to point out that the average for millions of examinations are wholly inapplicable to any given community. In such a case there might be practically no infested animals or there might be almost any ratio dependent on local and temporary conditions.

Since no adequate treatment for the disease is known, it is evident that there is still abundant need for educating the public regarding the source of trichinosis and the simple means of protection that may be taken against the infection. Much would be gained also by the extension to small plants of the federal regulations regarding the preparation of sausages and other pork products of a kind that are customarily consumed without being cooked.

ALLERGIC REACTION TO DINITROPHENOL

REPORT OF CASE

GERALD M. FRUMESS, M.D.

DENVER

Dinitrophenol has been introduced recently as a therapeutic agent in obesity,¹ its effectiveness arising by virtue of its ability, in small doses, to increase the basal metabolic rate. It is claimed that use of the drug is not accompanied by the unpleasant and dangerous side actions inherent in the use of thyroid gland extract, but its proponents state^{1b} that

The most important side action encountered was a skin rash, observed in eight patients, or 7 per cent of the entire series. This was manifested, usually after a one day prodrome of mild itching, by a maculopapular or urticarial type of rash. The itching was rather intense and with the urticaria there was considerable swelling. If the drug was withdrawn, the reaction subsided in from two to five days. In three of the patients, dinitrophenol treatment was successfully resumed after the skin reaction subsided without recurrence. This type of reaction is similar to the dermatitis medicamentosa of many agents but appears to occur somewhat more often with dinitrophenol in the dosage used than it does with some other common remedies. It seems to be the chief disadvantage in the use of the drug.

Anderson, Reed and Emerson² describe a case of toxicity from dinitrophenol resulting in a maculopapular erythematous eruption, pruritus, edema, and pain on motion of the joints. They pertinently suggest that this was an instance of "alpha-dinitrophenol allergy," since "it is apparently not an instance of small therapeutic amounts of the drug producing symptoms described for the known toxic effects of large doses." This suggestion is in keeping with the case I intend to describe, in which I believe I have shown a reaction to dinitrophenol to have been definitely allergic.

REPORT OF CASE

Mrs. S. K., aged 26, was put on a regimen of dinitrophenol by her physician, Jan. 16, 1934. The dosage was 1½ grains (0.1 Gm.) of the sodium salt twice daily. No untoward symptoms developed except increased sweating. In two and a half weeks she lost 2 pounds (0.9 Kg.) in weight. None of the toxic symptoms described by Tainter and his co-workers from overdosage resulted. The past history was negative except for the fact that the patient is definitely allergic. Ingestion of various foodstuffs has at times given rise to one or two urticarial wheals of a transitory character. The foods indicted are among those commonly blamed for allergic manifestations—celery, strawberries and sea food.

I first saw her on the afternoon of February 4, seventeen days after she had started taking dinitrophenol. At this time she presented giant urticarial wheals the largest I had ever seen. Some were fully 8 cm. in diameter. They occurred on the trunk, buttocks, thighs and upper part of the arms. The face, hands and feet were almost free from wheals. The pruritus was intense. Careful questioning elicited two possible etiologic factors—beets, which she had eaten the previous night and dinitrophenol. I suggested that she stop the drug at once and report my suggestion to the physician who had prescribed it.

An injection of epinephrine (1 cc. of 1:1000) and the use of ephedrine sulphate, three eighths grain (0.024 Gm.) by mouth every three hours brought instant but only partial relief. The rest of the treatment consisted of saline catharsis and ingestion

of large quantities of fluids and alkalis. The diet was restricted to beef and rice, these articles being practically always non-antigenic.

Twenty-four hours later typical wheals still persisted, and there was intense angioneurotic edema of the hands and wrists, some swelling of the lips and eyelids, and pains in the joints. Suspecting from the presence of the urticaria and Quincke's edema, that the symptoms were allergic I withdrew 10 cc. of blood from a cubital vein of the patient, permitted it to coagulate, and injected 0.1 cc. of her serum intracutaneously into the back of her brother, S. G., a nonallergic individual at two different sites.

On the following day I elicited a positive Prausnitz-Kustner reaction. My technique and method of control were as follows. On one of the two treated sites I made a scratch and applied a small amount of dinitrophenol in powdered form, rubbing it into the scratch with physiologic solution of sodium chloride. Within three minutes a typical wheal and flare reaction resulted. On the other treated site I made a similar scratch and rubbed into it physiologic solution of sodium chloride without the drug. On an untreated site of skin I made a third scratch and here applied powdered dinitrophenol; neither of the last two scratch tests produced any reaction whatever.

At this time, forty-eight hours after the onset of the eruption the characteristics had altered markedly. Instead of the pruritic urticarial wheals there were large dusky erythematous blotches, tending to coalesce, distributed over the arms, legs and face. These patches were nonelevated and nonpruritic. The edema of the extremities and face had increased. I made a scratch on the forearm of the patient and applied a small amount of dinitrophenol diluting it with saline solution. A small wheal was produced at the site of inoculation, and there was immediately a generalized focal response. The dusky erythematous patches became bright red and were elevated above the surface of the surrounding skin and an intense itching commenced. This focal exacerbation persisted for about three hours. The reaction was somewhat reminiscent of the response of fixed phenolphthalein and antipyrine eruptions to ingestion of further quantities of those drugs.

Ninety-six hours after the onset of symptoms the eruption had disappeared with the exception of a few diffuse, purplish patches on the chin. A scratch test with dinitrophenol at this time again produced a local wheal and a recurrence of the erythema multiforme-like eruption on the face and the extremities.

Except for an intense yellow, presumably imparted by the drug dye, the urine was normal.

COMMENT

In addition to the case described, I saw one other case of urticaria following the use of dinitrophenol. The course of this case was identical day by day, with that of the one described. No passive-transfer (Prausnitz-Kustner) test was performed on this individual. Proof of the allergic nature of this eruption is therefore, wanting. Within the past week I have heard of at least six other cases of skin eruptions following the administration of dinitrophenol. I do not know how many of them were of the urticarial type. How numerous are the other instances in this community is a matter for conjecture. Certainly great quantities of dinitrophenol are being dispensed, judiciously and injudiciously, with and without a physician's prescription.

I believe I have definitely proved that my case of dinitrophenol eruption was allergic. The evidence afforded by the passive transfer of the antibodies in the patient's serum to a normal subject and their subsequent demonstration by the Prausnitz-Kustner method is incontrovertible. In addition to this the local and focal response of the skin of the patient to applications of the drug by the scratch method quite definitely indict the drug as the cause of the eruption. I do not maintain that every eruption following the use of dinitrophenol is allergic in character. But any drug

2 Anderson H. H., Reed A. C. and Emerson G. A. *Toxicity of Alpha Dinitrophenol* J. A. M. A. 101: 103 (Sept. 30) 1933.

which produces pathologic skin manifestations in 7 per cent of those to whom it is administered must be used with caution.

Tamiet and his associates maintain that the use of the drug may be renewed with impunity after the skin reaction has subsided. I, for one, would not take the responsibility of telling my patient that it is safe for her to resume the use of dinitrophenol after her skin is again normal, any more than an allergist would tell an asthmatic patient who is allergic to egg white that he might eat eggs again after his asthmatic spasm has subsided.

SUMMARY

1. Alpha-dinitrophenol produces skin eruptions in a large percentage (at least 7 per cent) of those to whom the drug is administered.

2. These eruptions occur when nontoxic amounts of the drug are used.

3. Some of these eruptions are definitely allergic, specific antibodies being produced in some individuals by ingestion of the drug.

4. In at least one case these antibodies were demonstrable by the Prausnitz-Kustner passive transfer test.

5. It is theoretically dangerous to resume the use of the drug after a skin reaction from its ingestion has subsided.

Clinical Notes, Suggestions and New Instruments

TRICHINOSIS DEMONSTRATION OF THE PARASITES IN THE BRAIN

EDGAR R. PUND, M.D. AND RALPH MOSTELLER, M.D. AUGUSTA, GA.

This fatal case of trichinosis is worthy of report for several reasons. At autopsy the parasites were found in the brain. Symptoms of encephalitis began three weeks after vaccination against smallpox. Eosinophilia was absent; the patient was a child, aged 11 years, and incidentally the child also had sickle-cell anemia. A clinical diagnosis was made of encephalitis of unknown etiology, possibly a delayed postvaccinal complication. Unfortunately, trichinosis was considered neither at the bedside nor in the morgue and the correct diagnosis was made from a study of the microscopic sections of tissues removed at autopsy only by chance was a small piece of voluntary muscle included in the sections.

REPORT OF CASE

History.—W. A., a Negro boy, aged 11 years, entered the hospital Jan. 3, 1933, with an admitting diagnosis of encephalitis of unknown etiology. There was a past history of mumps, whooping cough and chills and fever. Three weeks prior to the onset of the present illness he had been vaccinated against smallpox, and other than slight discomfort from the vaccination there was no untoward reaction. It was noted by the parents that he did not "play very well" during the Christmas holidays. For three days prior to admission he had complained of stiffness of the right thigh and left elbow and of pain in the abdomen. On the first day of his illness he had vomited twice. There was no noticeable fever. On admission he complained of pain on motion of both arms and legs.

Physical Examination.—The patient was fairly well developed. He lay quietly in bed in no pain or distress unless moved. He appeared drowsy. Movement of the limbs produced intense pain. There was moderate hypertonicity of all muscles, particularly in the extremities. There was slight generalized edema which was more pronounced in the dependent parts of the body. He could not open his mouth sufficiently wide for an examination

of the pharynx. The tongue was moved with difficulty, he was unable to extend it from the mouth and its surface was heavily coated. The cervical and inguinal lymph nodes were palpable. The eyes had a dull appearance, the pupillary reflex to light was a little sluggish and there was some edema of the eyelids. Inspiration was limited and respiration was of a costal type. The abdomen was slightly distended, tenderness could be elicited along the costal margins and slight rigidity was noted in the abdominal muscles. The spleen was not palpable. Dorsally there was considerable tenderness over the kidneys. The shoulder, hip and knee joints were tender to touch and all movement elicited pain. The arms were held flexed at the elbows and could not be extended. There was such hyper-tonicity of the muscles of the lower extremities, especially of the flexor groups that he was unable to stand or walk. The reflexes were much diminished or absent, Kernig's sign was absent.

Course.—On admission his temperature was 101.6 F. and continued during the course generally between 99 and 102. On one day only did the temperature reach a height of 103 F. His respiration varied from 24 to 32 per minute and the pulse rate from 112 to 128. The leukocyte count was always elevated; the lowest of six counts was 12,200 and the highest 16,800 cells per cubic millimeter. The erythrocyte count was 4,600,000 soon after admission and 3,900,000 three days prior to death, and the hemoglobin estimate was 75 per cent and 70 per cent respectively. On the fourth day in the hospital the differential count was polymorphonuclear neutrophils, 88 per cent, large lymphocytes, 3 per cent, small lymphocytes, 9 per cent. Four days before death it was polymorphonuclear neutrophils, 79 per cent, large lymphocytes, 6 per cent, small lymphocytes, 13 per cent, transitionals, 1 per cent, eosinophils, 1 per cent. Examination of the urine was persistently negative. On the third day of admission the spinal fluid pressure was 6 mm. of mercury, the fluid was clear, the cell count was 35, globulin tests (Pandy and Ross-Jones) were negative, and the Wassermann reaction was negative. One week later the pressure was 8 mm. of mercury and the fluid was bloody (traumatic). The spasticity of the muscles improved gradually and in two weeks the patient was able to open his mouth, could use his arms, and frequently expressed a desire to sit up. The drowsiness and fever continued despite the improvement in the condition of the muscles. On the eighteenth day he seemed more drowsy than usual. The following day he became delirious and from the delirium passed into coma and died on the twentieth day after admission which was the twenty-third day of his illness. An autopsy was performed three hours after death.

Autopsy.—The body was wasted, it was 140 cm. long and weighed about 25 Kg. There were no gross structural changes in the brain except diffuse congestion. Routine sections from the cortex, basal ganglia, medulla and cerebellum were examined and in all sections minute inflammatory foci were observed. Glial cells and a few plasma cells, lymphocytes and polymorphonuclear leukocytes with an occasional endothelial leukocyte were the cellular constituents of these foci. Very rarely there was seen a syncytial mass with five or six nuclei which resembled the nuclei of the glial cells. In the center of many of these foci a granular wormlike parasite was seen, the embryo of the trichina, one of which is shown in the accompanying illustration. A few parasites were fragmented, but most of them were well preserved and intact. The foci were irregularly distributed in both the white and gray matter and sometimes were near a capillary. They were more numerous in the basal ganglia, medulla and cerebellum than in the cortex. The pia of the cortex and medulla was diffusely infiltrated with a few lymphocytes, plasma cells and polymorphonuclear leukocytes, and a like infiltration occurred around and in the adventitia of the larger blood vessels of the cortex and of the basal ganglia. The infiltration about the vessels was unevenly distributed, with a tendency to be focal. All of the blood vessels were engorged. Many of the neurons in all sections exhibited chromatolysis, pyknosis and sometimes neuronophagia. Of the choroid plexus there was nothing unusual.

The peritoneal cavity contained about 100 cc. of slightly turbid fluid. Each pleural cavity contained about 200 cc. of clear fluid and the pericardial fluid was in excess. The thymus was wasted. The lungs were small, the lower lobes were not

well distended, and early suppuration was noted. An incidental finding was a small tracheal cyst the size of a grape attached to the trachea at the bifurcation. The heart weighed 120 Gm. The chambers were dilated and the myocardium was pale and flabby. Microscopically there were scattered irregular foci of degenerated fibers, and these areas were infiltrated with a few lymphocytes, plasma cells and an occasional polymorphonuclear leukocyte. In a few foci, slight fibroblastic activity was evident. The liver weighed 985 Gm. The hepatic cells were cloudy and contained an excess of visible fat. The spleen weighed 50 Gm. In a section from one suprarenal gland a microscopic focus of necrosis infiltrated with polymorphonuclear leukocytes was seen in the reticular and the inner half of the fascicular zones. The kidneys, weighing 180 Gm, were in a state of cloudy swelling. The gastro-intestinal tract showed nothing unusual. A section from a mesenteric lymph node revealed no unusual changes. Trichinosis was not suspected in the morgue and unfortunately no specimens of voluntary muscle were selected for microscopic study, but a small tab of voluntary muscle was adherent to the section of the prostate. In this minute tab, about the size of the microscopic field of the two-thirds objective, six encysted trichinae were seen and about these there were a few lymphocytes, plasma cells and polymorphonuclear leukocytes. The erythrocytes in all sections were sickle shaped.

COMMENT

It is rare to find the trichinae in the brain, and although our search in the literature was not complete we could find only four reports. In 1906 Channing¹ stated that in an autopsy at the Boston City Hospital he had found in the cerebrum a few areas of cellular infiltration chiefly of endothelial and neuroglial cells with an occasional leukocyte or lymphocyte, and in some of these foci a part of a trichina embryo was seen. In 1916, from a study of fourteen cases of trichinosis, Salzer² wrote "Trichinae occurred abundantly in the brain and on injection of such tissue into animals the disease can be produced, the eosinophilia being more marked than in any other form of production of the disease." He did not describe the lesion nor did he state whether he saw the parasites or only recovered them by animal transmission. Hassin and Diamond³ in 1926 described what they termed the second case in the literature in which the invasion of the brain by trichina larvae had been demonstrated. Their case was similar in many respects to ours, a boy, aged 14 years, dying twenty-two days after the onset of symptoms. They reported, however, an eosinophilia of 21 per cent and at autopsy trichinae were found in the meninges, around the vessels of the brain and in the choroid plexus as well as in the substance of the brain. Besides the focal areas they noted toxic changes in the brain neuronophagia, satellitosis and focal encephalomalacia. They considered these changes the more dangerous condition because they were found without the presence of parasites in the brain of another fatal case of trichinosis. There was also hyperplasia of the spleen. In 1927 Gruber and Gramper⁴ reported a case in which they found glial nodules in the brain and cord containing young trichinellae and infiltration of the meninges and about the vessels.

In acute trichinosis the larvae are carried throughout the body by the blood stream and in 1909 the parasites were first demonstrated in the blood of a patient by Herrick and Janeway.⁵ MacCallum⁶ states that the trichinae lodge in every other tissue but appear to find conditions unsuitable and never develop there, indeed, they are rarely found anywhere else than in the skeletal muscles. However, besides in the brain blood

and meninges the larvae have been found in the placenta, milk of a nursing woman, excised mammary gland, pleural fluid, retina, peritoneal fluid, pus of a furuncle, heart, lungs, bile, pancreas, kidneys, and mesenteric lymph nodes. And Gruber⁷ thinks that the histologically demonstrable effect of straying trichinae in the pathologic picture in trichinosis has perhaps not been considered enough, probably because the picture has been eclipsed by the predominating disorder of the muscles. In this respect it should be noted that in our case there was a degenerative and exudative myocarditis, which was probably responsible for the transudate in the serous cavities. Because the exudate in the myocardium was similar to that seen about the parasites, it is possible that the myocarditis was caused by the presence of parasites that had degenerated and disappeared. Such a lesion in the myocardium associated with the presence of the trichinae was observed by Horlich and Bicknell.⁸ In the cases reported by Gruber and Gramper⁴ and Hassin and Diamond,³ in which the trichinae were found in the brain, similar myocardial lesions were found.

A number of observers have particularly noted encephalitic and meningitic symptoms in cases of trichinosis, and in 1914 Van Cott and Lintz⁹ first demonstrated the trichinae in the cerebrospinal fluid. Our case was of particular interest because the onset of the illness followed vaccination against smallpox and it was thought to be possibly a case of postvaccinal encephalitis. Because of the attention attracted by various kinds of

Section from the lenticular nucleus, showing a nodule with a trichina in the center slightly reduced from a photomicrograph with a magnification of 500 diameters

encephalitis today, in the differential diagnosis it is well to bear in mind meningo-encephalitis caused by the trichina.

The third point of interest is the absence of eosinophilia. Brown¹⁰ in 1898 first called attention to the presence of eosinophilia in cases of trichinosis and this sign is commonly considered of diagnostic importance. Adamy¹¹ states that the conclusive symptom in differential diagnosis is a marked eosinophilia. Chasanow¹² considers eosinophilia the most important characteristic of trichinosis, and Conner¹³ states that an absence of eosinophilia throughout the entire course seems to be very rare. On the other hand, many observers have noted the absence of eosinophilia especially in severe and fatal cases.

of trichinosis. According to Pepper,¹⁴ eosinophilia is present in almost every case but may be absent in extremely severe or fatal cases. Reifstein and his associates¹ in a review of the literature state that those cases failing to exhibit an eosinophilia at all times during the acute states are to be regarded as the ones in which recovery is most unlikely. Hickling¹⁶ and Walker¹⁷ report that eosinophilia may be absent in the acute phase and later develop in the convalescent period. Aldridge¹⁸ finds that an overwhelming infection may show no eosinophilia, and the one fatal case of twenty reported by Willett and Pfau¹⁹ did not present eosinophilia.

It has been noted by Gruber,² Pepper¹⁴ and Messner²⁰ that trichinosis in children usually runs a milder course than in adults and according to Pepper¹⁴ diarrhea is more marked in the cases occurring in children and this probably explains the lack of severity of these cases. It is interesting to note that there was no history of diarrhea in our case nor did the patient suffer from diarrhea while in the hospital.

A final point of interest is the development of trichinosis in a case of sickle cell anemia. The degree of sickling of the erythrocytes was not determined during life, so that it cannot be stated whether this patient was an active or latent sickler. At autopsy it was observed that the greater part of the erythrocytes were sickle shaped and the spleen presented the characteristic picture of sickle cell anemia, that is the congestion and pooling of the blood about the lymph nodes. It is possible that this condition played no part in the fatal outcome of the disease, yet in our experience patients with sickle cell anemia have a poor resistance to all types of infection.

SUMMARY

In a fatal case of trichinosis the larvae were demonstrated in the brain.

The onset with symptoms of encephalitis followed vaccination against smallpox.

During the course there was no diarrhea and no eosinophilia.

The patient was a child with sickle cell anemia.

A METHOD OF CONTROLLING POLLEN REACTIONS

RAYMOND M. RICE, M.D., COUNCIL BLUFFS, IOWA

Pollen reactions in the early days of pollen therapy were so frequent and so severe as actually to menace continuance of this method of therapy in the treatment of pollen hay fever and asthma. Many physicians discontinued pollen therapy on this account. The danger and frequency of reaction have been reduced in several ways so that at the present time they rarely occur unless some gross error in technique is made.

Cooke¹ suggested a most effective method of controlling reactions after they occur through the use of a tourniquet applied above the site of injection of the extract.

Duke² decided that a great many violent reactions after pollen injections, given with flawless technique were due to extract getting into veins, capillaries, arterioles or lymph spaces, and he devised a method that seems practically perfect so far as danger to the patient or severe sudden reaction is concerned. The method amounts to adding epinephrine and

ephedrine to the pollen extract and adding diluting fluid to make a total volume of 1 cc. The mixture is then injected subcutaneously distal to a tourniquet around the arm, which prevents any chance of rapid entry of pollen material into the general circulation. The tourniquet is left in place several moments to give the epinephrine and ephedrine sufficient time to constrict the vessels around the pollen extract so that absorption becomes of necessity slow and gradual. He mentioned delayed reactions, which may occur rarely after several hours. These were mild and could easily be controlled by reapplications of the tourniquet.

Insley³ reported a case similar to mine and applied Cooke's idea to the treatment for overdosage of epinephrine. I have followed Duke's method of therapy for two years and have had no reactions of importance except in the case reported here in which a patient by accident was given a gross overdose of extract. Also the only ill effect that I have observed from epinephrine mixed with pollen is an occasional patient who feels nervous and has palpitation after its use. This can be controlled within a matter of seconds by light constriction above the point of injection of the extract.

The gross overdose in pollen extract to which I referred was in a man aged 24, whom I was treating coseasonally with very tiny doses of extract, such as 0.02 cc of a 1:10,000 solution of round pigweed and short and giant ragweed. After obtaining relief for from one to three days after each injection he was given by mistake 0.04 cc of a 1:10 dilution. He immediately complained of an intense burning at the site of injection which led to a quick detection of the error.

Although a tourniquet was in place above the area a blood pressure cuff was substituted to give more complete control of absorption. Epinephrine was then injected surrounding the extract site. For the next hour the pressure in the cuff was released for only a few seconds at a time, the patient experiencing uncomfortable epinephrine symptoms with the longer periods. The palm of the hand and the arm itched severely and the area surrounding the extract became red, hot and swollen. As the epinephrine became less bothersome the cuff was allowed to remain open for a period of about forty seconds. Immediate and violent hay fever symptoms followed. The nose closed completely and the conjunctivae became injected.

Epinephrine was given in the opposite arm and another cuff was applied to control any discomfort that might follow. One side of the nose partially opened when it became necessary to close the cuff because of heart pound.

The pollen cuff was again released and absorption allowed until the skin over the shoulder began to itch. The resultant increase in symptoms was then relieved by release of epinephrine from the opposite arm.

The period of pollen release varied between thirty seconds and one and one-half minutes for the next three hours, each interval being followed by release of epinephrine. The patient experienced little discomfort other than the nasal stoppage and itching of the skin due to a mild urticaria. He had no evidence of asthma at any time.

Four hours after the administration of the extract, release of the pollen cuff resulted in no increase in symptoms. After another half hour of observation the patient was allowed to go home. He felt perfectly well, his nose and eyes were symptom free and only a few itching wheals remained. That evening while he was at home a mild urticaria appeared but it faded completely without treatment. His arm was very sore for two days but symptoms of general reaction were absent. After three days his hay fever recurred so that pollen in correct dosage was resumed and continued throughout the remainder of the season, producing satisfactory relief.

SUMMARY

Vasoconstrictors added to pollen mixtures and given distal to a tourniquet make possible a controlled dose.

Epinephrine given in the opposite arm with the absorption rate controlled by a tourniquet combined with tightening and release of the tourniquet over the pollen site gives a very effective treatment method for pollen overdosage.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE. IT IS THE FIRST OF A SERIES OF ARTICLES PRELIMINARY TO THE COUNCIL'S INVESTIGATION OF OPHTHALMOLOGIC APPLIANCES.

H A CARTER Secretary

TINTED LENSES THE PRESENT DEAL

W W COBLENTZ, PH D, D Sc
WASHINGTON, D C

At the request of the Council on Physical Therapy, I have inquired into the recent production of tinted lenses and the advertising claims made for them. At the outset it may be stated that, while during the past two years there has been some improvement in the fairness of the claims made in the advertising literature, there is still a long way to go in the presentation of relevant facts as distinguished from unproved theories.

It is a safe guess that these advertisements are not seen by many indiscriminating laymen but are read mainly by trained ophthalmologists. It would therefore be a sad reflection on the intelligence of such readers to assume that they accept the "ballyhoo" part of the advertising as proved facts of importance in their profession.

Two years ago, when the advertising situation in connection with and preparatory to the presentation of data on the transmissive properties of tinted lenses was reviewed,¹ the advertising literature regarding tinted lenses was replete with claims, some of which were evidently the result of ignorance, while others were based on unproved theories. It was then a common occurrence to read "They increase visual acuity," "they eliminate glare," "they do not distort colors," "they are non-habit forming," and so on.

One kind of tinted lens advertised at that time was supposed to let in light but shut out glare just as though glare was not a function of the intensity of the incident visible radiation light and that the lens was some sort of "one way" light path or, to be more nearly exact, an automatic shutter capable of regulating the light intensity to meet the need for clear vision.

Another advertisement recommended dark glasses for night driving, apparently overlooking the fact that if the glass was sufficiently dark to protect the eye from the glare of an oncoming automobile headlight it would be impossible for the wearer to see in driving, particularly on a black-top road on a cloudy night.

Still another advertiser introduced a little farce by citing the serial number of the patent supposed to contain the formula used in the manufacture of his glass. The patent cited related to a "composition of matter" which was claimed to be "productive of a brilliant glass of a transparent beautifully red color," whereas the advertised product was sky blue.

In contrast with conditions two years ago, at present the advertising situation seems to be somewhat improved. Perhaps this is because some of the incipient claims with alluring advertising possibilities have died in embryo. Take for example the question of eyestrain induced in long-distance automobile driving. This cannot be eliminated by a special laminated windshield, which was the dream of at least one inventor. For, aside from the fatigue caused by strong sunlight reflected from a light-colored road or from snow (which is easily eliminated by dark sky shade 3 lenses), probably, the chief cause of painful eyestrain

and subsequent headache is a difference in refraction of the unaided eyes. Judging from personal experience, relief from the latter type of eyestrain is obtained by wearing suitably corrected spectacle lenses that give clear vision at a suitable distance ahead of the motor car, without serious impairment of the clearness of vision of far distant objects.

Following the recent vogue, from the cosmetic side, the spectacle advertisements are up to date. Like the child's go-cart, the spectacle frames are now "streamlined," and some are made in colors to match the gowns.

Judging from recent advertisements, the production of new tints in lenses has run its course, at least temporarily. Some of the old standbys are still mentioned, one "cerulean blue," apparently under a new trade name. Just how the light-tinted lenses can reduce real glare² is not made clear, granting that they do mitigate a "little glare." Lenses in which the tint is invisible, except when viewed edge-on, are no more useful in reducing glare than common window glass. If there is one question that needs debunking it is the "increase of vision" and the elimination of "eyestraining glare" by wearing light-tinted lenses.

Another question that needs "debunking" and clarification is the extent to which the eye is irritated or kept healthy by wearing lenses that either admit or exclude (depending on the particular product that is being promoted) short wavelength ultraviolet radiation, known to prevent rickets, and hence by inference effective in "vision vitality." When one considers that most objects are viewed in reflected light and that, as a general property, they (except snow) highly absorb the ultraviolet relative to the visible rays, the presence or absence of the ultraviolet rays seems to be of minor importance physiologically and for promoting the sale of lenses. As pointed out in the previous paper, ophthalmologic research will serve a useful purpose in clarifying these questions.

With this temporary let up in the exploitation of tinted lenses, the merits of new types of wide-vision lenses (the "Punktals" and so on) are being extolled. According to recent investigations, the importance of this improvement appears to be greatly overestimated. Just how this type of lens will benefit the average wearer, and just why he should be put to the extra expense of procuring a pair, is questionable. It is true that such a glass may aid a little in the clearness of perception by indirect vision, but once the attention is called to an object on the sideline, the average person will turn the head and hence will profit but little by the use of such a lens in viewing an object in straight ahead vision. In other words, for a reading lens that may have to be changed frequently and that is used only in a sedentary occupation, it is not clear why the many wearers should be put to the expense of procuring a special lens that may perhaps be necessary only for the unfortunate few. For constant wear, in vehicular traffic such a lens should serve a useful purpose.

European optometric journals carry advertisements of new laminated, nonshatterable, splinterless, safety lenses claiming absolute and constant clarity, guaranteed for a year. Apparently these are plane lenses of clear glass (unless otherwise ordered) for protection in motoring. At any rate but little is said regarding corrected lenses (though to "correct and protect" is mentioned). Perhaps this is to be expected, in view of

² The question of the elimination of glare is discussed in THE JOURNAL AUG 23 1930 p 593. It is shown that only dark shades can eliminate high intensity.

the probable difficulties that may be experienced in grinding a complicated prescription lens on a compound, three-piece medium, consisting of two pieces of glass and an intervening, flexible, lamination of a cellulose material that is subject to changes in dimensions as a result of variations in temperature and by evaporation of the plasticizer.

Without desiring to dispute the importance of eye protection as a general proposition, nevertheless, lest the introduction in this country of such laminated glasses be accompanied by the foregoing exploitation now somewhat in abeyance, it would be desirable to have statistics on the frequency of eye injury in motor-ing and in other similar pursuits which are subject to infrequent hazards, as distinguished from the occupational hazards from relatively large flying particles, such as are encountered by machinists, stone cutters and foundry workers.

For protection from flying particles a single rather thick (3 mm.), clear glass lens is prescribed (Federal Specifications for Chippers Goggles, G G G—G-501). In addition to the extra thickness, extra strength is obtained by a special heat treatment which results in a uniform radial fracture when the lens is broken by sudden impact. Apparently preference is given to a single piece lens to insure clearness of vision, instead of a laminated lens of uncertain performances. However, it would be a pessimistic view to assume that a laminated lens, having the optical properties of a single lens cannot be made. Whether the newly developed laminated glass is the utopian product sought awaits further investigation.

Council on Pharmacy and Chemistry

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORT PAUL NICHOLAS IFFCH, Secretary

PHENYLMERCURIC NITRATE AND PHENYLMERCURIC CHLORIDE

Phenylmercuric nitrate and phenylmercuric chloride were first prepared by R. Otto in 1870. Although these substances have been known for more than sixty years, their effects on animals, bacteria and fungi, their so-called "biological characteristics," seem not to have been studied until Weed began to investigate them at Iowa State College in 1927 and 1928. In his thesis, Weed¹ states that Kharasch also investigated at about this time a related group of compounds as possible agents for the control of seed and plant diseases. The investigations of Weed were continued in association with Dr. Ecker in the Institute of Pathology at the Western Reserve Medical School in Cleveland. Methods of preparation of the compounds were perfected, the compounds were found to be strongly bactericidal and fungicidal, and indications of their possible clinical usefulness were obtained.²

Steps to make the compounds available to physicians were begun by Dr. Weed in 1932. The J. H. R. Sales Corporation, Chicago, has presented phenylmercuric nitrate and phenylmercuric chloride for the consideration of the Council. The following dosage forms were submitted:

1. Phenylmercuric nitrate 1:2,000 in a mixture of water 90 per cent and diethyleneglycol 10 per cent by weight.

1. Weed, L. A. The Biological Properties of Certain Organic Mercury Salts. thesis, Department of Pathology, Western Reserve University, May 15, 1932.

2. Weed, L. A., and Ecker, E. E. (a) The Utility of Phenyl Mercury Nitrate as a Disinfectant. *J. Infect. Dis.* 49:440-449 (Nov.) 1931. (b) Bactericidal Action of Phenyl Mercury Nitrate. *ibid.* 51:309-314 (Sept-Oct.) 1932. (c) Phenyl Mercury Compounds—Their Action on Animals and Their Preservative Values. *ibid.* 52:354-363 (May-June) 1933.

2. Phenylmercuric nitrate 1 per cent, diethyleneglycol 99 per cent by weight.

3. Phenylmercuric nitrate 1/10 per cent, remainder glycerin by weight.

4. Ointment containing phenylmercuric nitrate 1 part in 1,500 parts by weight of an odorless absorption (oxycholesterin) base.

5. Jelly containing 1 part of phenylmercuric nitrate in 1,500 parts by weight of a mixture of gum tragacanth, glycerin and water.

6. Phenylmercuric chloride 1:30,000 in 0.85 per cent solution of sodium chloride.

Each of these compounds is described by the manufacturer as 'a very potent bactericide and fungicide of extremely low toxicity' and is recommended for "general disinfection and for the treatment of bacterial and fungal diseases." Some of the dosage forms have been devised for special uses.

Phenylmercuric nitrate is said to be $C_6H_5HgNO_3$ and phenylmercuric chloride, C_6H_5HgCl . Weed and Ecker have repeatedly emphasized the need of preparing these compounds according to the method perfected by them in order to obtain products of maximum antiseptic power and minimum toxicity for man and animals. In a letter to the Council's secretary, May 15, 1933, Weed expressed the opinion that these compounds obtainable from several manufacturers are not as satisfactory as the compounds prepared by him or according to his method under the supervision of himself and Ecker. Weed has stated for example, that the preparations of phenylmercuric nitrate obtained from one manufacturer in 1932 were unstable, did not have the same melting points as his preparation and were irritating, that preparations of phenylmercuric nitrate obtained by Weed and Ecker from another manufacturer were more granular, had different melting points, and were more irritating than Weed's preparations and that phenylmercuric nitrate obtained by Weed and Ecker from still another manufacturer was more like their own product but was less germicidal. It is evident that, if different brands of these compounds are to be considered by the Council, it will be necessary to determine the special properties of each brand and that reports on their clinical use should contain information on the brand used.

The methods of preparation of phenylmercuric nitrate and phenylmercuric chloride set forth in the presentation to the Council for the products of the J. H. R. Sales Corporation are the same as those published by Weed and Ecker.³ On the basis of molecular conductivity measurements these authors concluded that phenylmercuric nitrate is highly dissociated in water. The surface tension of a saturated aqueous solution of phenylmercuric nitrate is that of distilled water⁴ and the solution is neutral to litmus.

TOXICITY FOR MAN AND ANIMALS

Gunter-pigs, rats and mice were given a saturated solution (1:1,250) of phenylmercuric nitrate as their only source of water during periods of two to three weeks. Only a few animals in several large series showed ill effects as the result of ingestion of the compounds.⁵ One series of 10 mice was maintained on a 1:2,000 solution of phenylmercuric nitrate as the sole source of water for ten weeks without apparent ill effect (Birkhaug).

Ten cubic centimeters of a 1:1,250 dilution (0.008 Gm. of phenylmercuric nitrate) injected intraperitoneally into rabbits did not produce any symptoms of poisoning. In an occasional animal this solution injected intravenously into rabbits produced edema of the ear but no other symptoms of intoxication.⁶

Later Weed and Ecker^{2c} determined that the "immediate" minimal lethal dose of phenylmercuric nitrate for rabbits when injected intravenously was 1 cc. of the saturated aqueous solution (1:1,250)⁴ per hundred grams of body weight. The chief lesion produced was 'acute nephrosis, typical of mercury poisoning.' The "cumulative" lethal dose was not accurately determined. Irrigations of the bladders of rabbits with a 1:50,000 solution of phenylmercuric chloride in physiologic solution of sodium chloride did not produce inflammation.

Birkhaug⁵ found that the minimal lethal dose for rabbits on intravenous injections was 0.01 Gm. of phenylmercuric nitrate.

3. Weed and Ecker footnotes 2a and 2c.

4. The Council has been informed by the firm that the solubility of phenylmercuric nitrate as now marketed is about 1:870 and that of phenylmercuric chloride about 1:20,000.

5. Birkhaug, K. E. Phenylmercuric Nitrate. *J. Infect. Dis.* 53:250-261 (Sept-Oct.) 1933.

(calculated mercury content 0.0059 Gm) per kilogram, less than one half the intravenous lethal dose found for inctaphen which contains about the same amount of mercury. Birkhaug determined also that the minimal lethal dose of phenylmercuric nitrate for rabbits, when administered by stomach tube was approximately 48 cc of a 0.067 per cent solution per kilogram—approximately three times the lethal intravenous dose. The convoluted tubules of the kidney were especially damaged. Injection of the compound into the tissues caused edema and pain.

The effect of these compounds on man are of special interest. Weed and Ecker^{2a} stated in their first paper in 1931. When phenylmercuric nitrate was applied to the human skin it had no effect. When it was used on the mucous membrane of the mouth a definite astringent action was felt. One person received 250 cc of the saturated solution 1:1,250 by mouth, with no signs of intoxication. Only a rise of 20 points in the pulse rate was noted.

Birkhaug,⁵ using two commercial preparations of phenylmercuric nitrate, ingested four 0.04 Gm doses of the crystalline product in enteric coated capsules within twenty-four hours. 'Slight abdominal pain and loose passages occurred about thirty hours from the beginning of medication.' No albuminuria was noted. Birkhaug ingested "repeated series of tablets containing 0.01 Gm of the crystalline compound twice or thrice daily for periods of one week without inflicting untoward symptoms and signs of mercurial toxicity."

It is apparent from these studies that phenylmercuric nitrate is a mercurial of relatively low toxicity for man and animals. Phenylmercuric chloride appears to have the same low toxicity. On the other hand, Biskind⁶ noted that while application of a 1:1,250 solution of phenylmercuric nitrate to the vagina did not cause irritation, a 1:750 solution in 10 per cent alcohol produced a "chemical burn". Levine⁷ found seven patients who developed "mercurial burns" from applications of these compounds to the skin. Biskind and Levine used products prepared by Weed and Ecker.

Although the toxicity of these compounds is less than that of some other mercurials, it is obvious that claims based on this property must be advanced with caution. It is to be expected that different brands of the products may show greater toxicity and capacity to irritate the skin than others and that some sensitive individuals may be poisoned or "burned" by doses that do not produce disturbance in others.

EXCRETION

There is little or no published information on the excretion of mercury following the ingestion or injection of phenylmercuric nitrate or phenylmercuric chloride. The chief contribution to knowledge of the distribution of phenylmercuric nitrate in the body which is probably converted to the chloride in the body fluids and its excretion in the urine is the paper by Birkhaug,⁵ published late in 1933. The evidence presented by Birkhaug is not chemical but indirect based on the determination of the bactericidal action of blood, bile, body fluids and urine of rabbits, dogs and man after the ingestion or injection of phenylmercuric nitrate. He found that within thirty minutes after the oral administration of the compound in rabbits the urine began to show antiseptic action (bacteriostatic action). Finally, after the oral administration of 20 cc of the 0.067 per cent solution of phenylmercuric nitrate every two hours for fourteen hours to a rabbit weighing 2.160 Gm the antiseptic (bacterial inhibition) values for the urine were against *Staphylococcus aureus* 1:10,240 against *B. coli* 1:160 against *Streptococcus haemolyticus* 1:20,480. Antiseptic concentrations obtained in the blood of this animal reached 1:640 for *Staphylococcus aureus*, 1:1,280 for *Streptococcus haemolyticus*, and 1:12 for *B. coli*. When this animal (and other animals) was killed twenty-four hours after the beginning of the experiment the urine, cerebrospinal fluid, fecal fluid in the cecum and bile were found to have noteworthy antiseptic properties. Bile obtained by fistula drainage from two dogs

were found to have high antiseptic capacity after oral administration of 50 cc of the 0.067 per cent solution of phenylmercuric nitrate. Infections of the biliary tract in these animals, one due to streptococci and the other due to colon bacilli, cleared up on the sixth day. Following intravenous injection of phenylmercuric nitrate in rabbits, Birkhaug⁵ found the blood antiseptic for staphylococci, streptococci, pneumococci and colon bacilli in significant titers. His own urine and blood had antiseptic property following the doses of phenylmercuric nitrate which he took by mouth.

Three points are brought forward prominently by these studies of Birkhaug: (1) The injected or ingested compound is widely distributed in the blood and body fluids (as determined by antiseptic tests); (2) the actively germicidal and bacteriostatic material is excreted in the bile and urine, and (3) oral or intravenous administration of phenylmercuric nitrate gives the blood, cerebrospinal fluid, bile, urine and intestinal contents antiseptic and germicidal properties.

Biskind⁶ reports the following data on the excretion of mercury in the urine after application of phenylmercuric nitrate solution to the vagina. The determinations were made by Miss N. E. Schreiber of the Department of Pharmacology, Western Reserve University. Twenty-four hour collections of urine obtained twenty-four hours after cessation of all treatment, from three women who had been taking daily douches of 1:25,000 solution of phenylmercuric nitrate for six weeks, showed total mercury contents (obtained as the free metal) of a trace (about 0.008 mg), 0.022 mg and 0.104 mg respectively.

It is pointed out by Biskind that these data are inconclusive, in that no information is available as to the quantity retained in the body or as to the fecal excretion. On general grounds, these figures are regarded as a "negligible output." Biskind states that in antisyphilitic therapy, where quantities of ionized mercury are absorbed, 'the urinary excretion of the metal is very much greater than that reported.'

BACTERICIDAL ACTION

The tests of the action of phenylmercuric nitrate and phenylmercuric chloride on bacteria *in vitro* in mixtures in salt solution, broth, and serum which have been made by Weed and Ecker⁸ and by Birkhaug⁵ were carried out by adequate methods with adequate controls. The details need not be repeated here. Examples of the results are as follows: Bacteriostatic or growth inhibiting power ranges up to 1:10,000,000 but usually operates best in dilutions of between 1:125,000 and 1:1,000,000. Birkhaug found it inhibitory against *Streptococcus haemolyticus* in a dilution as high as 1:150,000,000, it inhibited spore-bearing *B. subtilis* in a dilution of 1:12,000,000. *Staphylococci*, streptococci, gonococci, *B. coli*, *B. typhosus* and *B. subtilis* have been used in these tests. No reports on its action on tubercle bacilli have been published.

The bactericidal action determined according to the method of Reddish has been reported by these investigators to be unusually high. The phenol coefficient of phenylmercuric nitrate against *B. typhosus* was found by Weed and Ecker to be 625. Birkhaug⁵ found the following phenol coefficients against *Staphylococcus aureus*, 2,259, against *Streptococcus haemolyticus* 1,440, against *pneumococcus* 1,067, against *B. coli*, 640, against *gonococcus* 889, against *B. subtilis* 801. The presence of 50 per cent human serum reduces these values about 10 per cent for vegetative pathogens and about 40 per cent for the spore bearing *B. subtilis*. Birkhaug⁵ on the basis of his experiments makes the following comparison: Phenylmercuric nitrate surpasses the other disinfectants in the following order: merthiolate 1.6 times, metaphen 1.4 times, mercuric chloride 5.7 times, hexylresorcinol 9.6 times, mercurochrome, 43.4 times and phenol 120.2 times.

Weed and Ecker^{2b} showed that phenylmercuric nitrate in concentrations of from 1 part in 12,500 to 1 part in 37,500 killed various sporulating anaerobes in ten minutes. The organisms used in the tests were *Vibrio septique*, *B. histolyticus*, *B. chauvoei*, *B. welchii*, *B. tetani* and *B. sporogenes*.

FUNGICIDAL PROPERTIES

Weed¹ and Weed and Ecker^{2b} have shown that phenylmercuric nitrate inhibited the growth of most of the fungi that

6 Biskind I. H. Phenylmercuric Nitrate. Its Chemical Uses in Gynecology. 24. Preliminary Report Surg. Gynec. & Obst. 57: 261 264 (Aug.) 1933.

8 Weed and Ecker footnote 21 and 2b.

cause epidermophytosis when 1 to 5 per cent of the saturated (1:1,250) solution was added to the medium (dilutions of from about 1:125,000 to about 1:25,000). *Achorion violaceum* was more resistant than other fungi. On the basis of the results of these studies the compound has been used in the treatment of tinea and yeast infections of the skin with apparently good results, as will be noted in a subsequent paragraph on clinical applications.

The fungicidal properties of these compounds appear to have been clearly demonstrated by the results of tests with wood-destroying fungi. Weed's² studies have been confirmed by Hatfield.³ The use of these substances as preservatives of wood and as possible therapeutic agents in the treatment of fungous diseases of seeds and plants do not come within the scope of the Council. These investigations are mentioned because they give additional evidence on the toxicity of phenylmercuric nitrate for fungi.

PRESERVATIVE ACTION

Weed and Ecker²⁴ have published the results of experiments showing that enzymes, toxins and antigens are not interfered with nor destroyed by phenylmercuric nitrate or phenylmercuric chloride in concentrations that are capable of inhibiting bacterial growth. These tests were made with pepsin, trypsin, lysozyme, bacterial vaccines, precipitins, complement, diphtheria toxin and snake venoms. As has been stated, proteins are not precipitated by solutions of the nitrate or chloride.

NONCORROSIVENESS

Weed and Ecker²⁴ and Birkhaug⁵ have reported that phenylmercuric nitrate is not corrosive to metals (except aluminum) and that surgical instruments can be rapidly sterilized in aqueous solutions of it.²⁵ The data on which these conclusions are based are not presented in these papers. There is no reason, however, for doubting the general truth of the statement. On account of the physical peculiarities of surgical instruments with their hinges, joints, slots, tubes and crevices the Council believes that exploitation of the claim should not be allowed unless tests are made with each type of instrument.

SKIN STERILIZATION

Birkhaug,⁵ using the methods developed in his studies of skin sterilization by metaphen and other disinfectants, found that an acetone-alcohol-aqueous solution of phenylmercuric nitrate (0.034 per cent) disinfected the skin in three minutes. Tests were made with pinch grafts of rabbit skin and scrapings of human skin. This phenylmercuric nitrate solution was found to be more effective than similar solutions of mercurochrome, metaphen or tincture of iodine.

CLINICAL USE

Only two papers on the clinical use were available to the Council's referee at the time this report was made: one is by L. H. Biskind,⁶ the other that of Levine.⁷

Biskind⁶ reports on the results of the use of phenylmercuric nitrate in 100 cases of infection of the vagina and cervix (seventy cases in the first series, thirty cases in a second series). No attempt was made to select certain types of cases and all consecutive patients seen by the author showing a vaginal or cervical discharge were treated with phenylmercuric nitrate.

After preliminary examination, the taking of material for smears and cleansing the vagina and cervix with dry cotton pledgets, phenylmercuric nitrate solution was instilled into the cervical canal and applied to the vagina.

A tampon soaked with the solution was left in the vagina for twenty-four hours. A 1:1,250 solution of phenylmercuric nitrate was found finally to be most satisfactory and did not cause irritation. Daily douches with this material in a dilution of 1:25,000 were used also in many cases.

The cases treated were diagnosed as follows:

Thirty-two cases, gonococcic endocervicitis (positive for gonococcus).

Nineteen cases, gonococcic endocervicitis (not confirmed by laboratory examination).

One case, gonococcic vaginitis in a child.

Two cases, vaginitis following trauma of pessary or her douches.

Two cases, vaginitis due to *Trichomonas vaginalis*.

One case, abscess of Bartholin's gland, incision and drainage.

One case, postoperative rectovaginal fistula.

Forty-two cases, various forms of nongonorrheal endocervicitis, with a host of other conditions referable to the pelvis.

Among the cases of gonococcic endocervicitis, numerous patients had been resistant to various forms of treatment. When phenylmercuric nitrate was used, the discharge was reduced in from three to seven days. Biskind states that "phenylmercuric nitrate was used to clean up the secondary infection to eradicate the primary infection and then to maintain the cervix clinically free from infection while other treatment was used to heal associated conditions, e.g. silver nitrate or the actual cautery for cervical erosions." The Council's referee could not find in this paper any proof that the primary gonococcic infection was eradicated. The evidence indicates that these patients were observed during a period too short to determine whether or not permanent cures had been achieved.

All the other conditions were likewise greatly improved or cured except two cases of *Trichomonas* infection of the vagina, which were not affected by phenylmercuric nitrate. The rectovaginal fistula in one case closed rapidly under the influence of this antiseptic.

Biskind's report is highly favorable to phenylmercuric nitrate. It is to be noted that it is a "preliminary report." It is necessary to view these results and conclusions as Dr. Biskind does himself with caution, waiting for the results of more trials and longer periods of observation.

A typewritten report has been received from a physician, describing three cases of gonorrhea and four cases of leukorrhea treated with phenylmercuric nitrate. All the cases were cured in from one quarter to one half the time required by other germicides or in other words, instead of taking four to six months to cure the ordinary case, these cases have been cured in from six weeks to two months.

Other letters from physicians report favorable results of the treatment of peritoneal tuberculosis with a sinus tract and cases of osteomyelitis. In addition the Council has been supplied with a list of twenty-six physicians and three dentists who have used phenylmercuric nitrate in their practice.

Levine's report⁷ is an account of unusually favorable results in the treatment of "tinea and yeast infections of the skin" with phenylmercuric nitrate.

A lotion containing 1:1,000 phenylmercuric nitrate in an emulsion of gum tragacanth was found to irritate the skin. A 1:1,250 solution of phenylmercuric nitrate in a gum tragacanth lotion was decidedly "less irritating." (The referee noted that these irritating effects occurred with a preparation supplied by Weed and Ecker.) Finally, an ointment containing phenylmercuric nitrate in a concentration of 1:1,500 with 10 per cent glycerin in an oxycholesterin base, was found to be nonirritant and most satisfactory for the treatment of a variety of dermatomycoses.

Levine says: "Of 262 cases treated 205 were carefully followed up and the patients discharged as cured. The remaining 57 patients were seen but once after the beginning of treatment and the data in these cases remained incomplete. Of the 205 patients 193 had tinea and 12 had interdigital saccharomycosis. All the 193 cases of tinea were cured. The types of fungous infections were not specified according to the micro organisms but mention is made of tinea of the feet, tinea cruris, tinea of the axillae, tinea circumata of the glabrous skin, tinea versicolor and tinea of the scalp and face. In interdigital saccharomycosis usually a very refractory infection, Levine asserts, the length of time necessary to effect the cure varied from two days to four weeks, with an average of two weeks." In some cases recurrence was not observed within ten months. Levine concluded that phenylmercuric nitrate proved highly efficacious in the treatment of tinea and yeast infections of the skin "producing cures when other standard medicaments had failed."

Although the Council's referee has not seen these cases and has not had an opportunity to observe the treatment of ring worm infections with phenylmercuric nitrate, he thinks that the

evidence is not yet sufficient to warrant acceptance of the claim that this compound cures fungous infections of the skin so readily. Levine's paper presents considerable evidence that the drug may be very useful in these conditions.

DENTAL USES

There are no published reports on the use of these compounds in dentistry and stomatologic practice. According to the firm, Prof. T. J. Hill of the School of Dentistry and of the Institute of Pathology, Western Reserve University, has succeeded in incorporating phenylmercuric nitrate in dental cement, making the cement highly bactericidal and bacteriostatic, higher in these respects than any cement so far known. Dr. Hill has reported his observations at the Dental Association meetings at New York. The compounds are said also to have proved their effectiveness in the treatment of various forms of dental infections.

The Council wishes to secure close cooperation with the Council on Dental Therapeutics of the American Dental Association in reaching conclusions on the permissible dental and stomatologic claims for these products. They should, no doubt, be submitted by the manufacturer or distributor to the Council on Dental Therapeutics.

SUMMARY

Test-tube experiments have shown that phenylmercuric nitrate is a powerful germicide and fungicide of wide ranging effect and relatively low toxicity. Fewer tests have been made with phenylmercuric chloride, but it seems likely that the two compounds are equally active.

Experiments with animals indicate that the ingestion of phenylmercuric nitrate may lead to strong bacteriostatic and bactericidal effect in the blood, cerebrospinal fluid, bile, feces and urine.

It seems to be clearly indicated that phenylmercuric nitrate can disinfect the skin, disinfect instruments without corroding them and preserve biologic products against bacterial growth without destroying their specific properties and actions.

The few preliminary clinical reports available indicate that phenylmercuric nitrate and phenylmercuric chloride may prove to be useful chemotherapeutic agents for the treatment of some bacterial and fungous infections and are applicable to the treatment of a variety of disease conditions due to infection. This clinical evidence needs extension, confirmation and the test of time before it can be accepted as conclusive.

Phenylmercuric nitrate appears to be useful in dentistry and in stomatologic practice, but there is not sufficient clinical evidence covering these uses at the present time.

It is evident that many questions remain to be answered satisfactorily by the manufacturer who desires to have these products and their exploitation conform to the requirements of the Council.

Although phenylmercuric nitrate and phenylmercuric chloride seem to have great promise as germicides and as agents useful in bacterial chemotherapy, the Council's referee pointed out that the clinical studies, admittedly difficult to carry out conclusively, must afford the material on which the therapeutic efficacy of these compounds is to be determined.

The Council adopted the report of the referee to be published as a preliminary report on its consideration of phenylmercuric nitrate and phenylmercuric chloride. The Council voted further that the J. H. R. Sales Corporation be informed that its brands of phenylmercuric chloride and phenylmercuric nitrate will unless further conflicts arise be accepted for inclusion in N. N. R. (1) when acceptable evidence is submitted for every claim advanced (2) when acceptable advertising and labels are received and (3) when the A. M. A. Chemical Laboratory reports favorably on the tests standards and other chemical questions involved.

Since the statement of the Council's consideration was sent to the J. H. R. Sales Corporation the office of the Council's secretary has been informed that the entire patent manufacturing and sales rights of this firm on these phenylmercuric compounds have been acquired by a new corporation in Hamilton, Ohio organized under the laws of Delaware and named The Hamilton Laboratories, Inc.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

LIGHT'S FAIRY QUEEN CAKE FLOUR (BLEACHED)

Manufacturer—The Light Grain and Milling Company, Liberal, Kan.

Description—Hard winter wheat short patent flour, bleached.

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18 1932, p. 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-seventh ounce per barrel).

WHITE SWAN BRAND EVAPORATED MILK

Distributor—Waples Platter Company, Fort Worth, Texas.

Packer—The Page Milk Company, Merrill, Wis.

Description—Canned unsweetened sterilized evaporated milk the same as Page Brand Evaporated Milk (Sterilized, Unsweetened), THE JOURNAL, May 30, 1931, page 1872.

GOLDEN KEY WHEAT FARINA

Distributor—The Great American Tea Company, New York.

Packer—The Quaker Maid Company, Inc., New York.

Description—Hard wheat 'flour middlings' or farina the same as Mello-Wheat Breakfast Food. The Heart of the Wheat (THE JOURNAL, Oct. 1, 1932, p. 1175).

FAIRWAY BRAND FREE RUNNING TABLE SALT

Distributor—Twin City Wholesale Grocer Co., St. Paul and Minneapolis.

Packer—Morton Salt Company, Chicago.

Description—Table salt containing 0.7 per cent of added magnesium carbonate. Same as Morton's Free Running Salt. THE JOURNAL, May 14 1932, page 1745.

Claims of Manufacturer—This salt is for all table and cooking uses of salt. The added magnesium carbonate tends to preserve its free running qualities.

HEIMAN'S SPARKLING GOLDEN SYRUP

Distributor—Heiman Grocery Co., Trenton, Mo.

Packer—Bliss Syrup & Preserving Co., Kansas City, Mo.

Description—A table syrup, corn syrup flavored with refiners' syrup, the same as Bliss Pancake Golden Brand Syrup (THE JOURNAL, Oct. 28, 1933, p. 1393).

ACME-EVANS COMPANY WHITE PLUME BEST PATENT FLOUR (BLEACHED)

Manufacturer—Acme-Evans Company, Indianapolis.

Description—Short patent cake flour milled from soft winter wheat, bleached.

Manufacture—Selected soft winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-seventh ounce per barrel).

BODY BUILD AND METABOLISM

The influence of body build has long been of concern in the design and operation of motor cars. In the performance of the human body the possible significance of peculiarities in the physique of the individual—in unusual interrelations of body size and proportion—have only lately awakened serious interest. Today the claims of constitutional differences receive a respectful hearing. A recent writer¹ has remarked that the almost uncanny agreements found in applying the surface area formulas to basal metabolism of individuals of widely different body form, widely different proportions of body fat, and so on, have served to inhibit rather than stimulate interest in the effects of minor differences.

Structural form results from processes of unequal growth. This has been well expressed by Stockard² in an essay on human types and growth reactions. Equal growth, he states, in all directions from the original spherical egg would result in a sphere. Spheres may differ in size, but all are alike in form. Should the growth processes be exactly the same in two specimens, their final structures will also be exactly alike. Whenever the growth processes of the two differ, the resemblance is modified. Thus the problem of human types is a problem of growth and all individuals that may be grouped together under one type are individuals with closely similar growth histories. Stockard has further defined the consequences of unequal growth in relation to types of body build. There is a primary tendency to form an axis or line of growth. Following this, lateral growth takes place. Crudely stated, there is a tendency to attain length first and width later. Secondly, there is a certain degree of competition between these two tendencies so that as a rule the growth in width expresses itself only after the growth in length has worn itself down and become slower.

¹ White House Conference on Child Health and Protection, Growth and Development of the Child, Part III, Nutrition, New York, Century Company, 1932, p. 352.

² Stockard, C. R., Human Types and Growth Reactions, Am J Anat, 31: 261 (Jan.) 1923.

A corollary of such considerations naturally relates to unlike activities of organs, notably the thyroid, which regulate both the rate of metabolism and the rate of development. An interrelationship between physique and basal metabolic rate at once is suggested. It now seems to have been demonstrated by the recent investigations of Lucas and Pryor³ in San Francisco, from careful measurements of nearly 600 children. Slender-built children normally have higher basal rates than broad-built children of the same age sex group. High basal metabolic rates as measured by the conventional standards are the rule for the linear type group, whose width-length indexes of body build are well below average. The width-length index is an expression of the relationship of the width to the length of the body. It is obtained by measuring the diameter of the crest of the ilium and the standing height. The crest measurement is divided by the height to give the relative breadth of the body, or width-length index. This index represents width in percentage of standing height. Weight does not enter into the calculation. The size of the index increases with the relative breadth of the body.

It has been remarked that constitutional influences on basal metabolism may be of at least four kinds: those hereditary factors which affect body size and proportion; those which affect nervous organization; those which produce a tendency to leanness or fatness; aside from the endocrine functions and the endocrine factors themselves. The first of these, certainly, and probably others, may be traced to the chromosomes of the germ cells. No certain method is at hand of determining where chromosomal influences per se leave off and endocrine influences begin. The great varieties of body size and shape possessing perfectly normal and well balanced endocrine functions, different proportions of muscle mass, visceral mass, weight of skeleton, skin, and other connective tissue structures must produce considerable differences in the rate of basal heat production. The San Francisco study is a notable contribution to the perplexing problems of body build and metabolism.

THE CARE OF THE PREMATURE INFANT

In the deliberations of the White House Conference on Child Health and Protection, it was pointed out¹ that the handling of premature infants is so complicated that it is hard to decide which of their problems are nutritional, environmental, infectious or due to actual congenital anomalies or birth injury. In the past, more attention has probably been devoted to the nutritional aspects of the baby's regimen than to any other features of its management. Every one is aware that the heat regulatory mechanism at the beginning of extra

³ Lucas, W. P. and Pryor, Helen B., The Body Build Factor in the Basal Metabolism of Children, Am J Dis Child, 46: 941 (Nov.) 1933.

¹ White House Conference on Child Health and Protection, Growth and Development of the Child, Part III, Nutrition, New York, Century Company, 1932, p. 72.

uterine life is far from adequate in most species. In the case of the premature human infant it is by no means fully developed at birth, consequently, unless the infants are kept warm by the application of external heat the body temperature gradually falls, in some instances it fails to rise again, with detrimental or fatal consequences. The inability of the premature infant to regulate and maintain a normal body temperature is attributed largely to incomplete development of the nervous system, as a result of which there is an imperfect balance between loss of heat and production of heat. Talbot² has observed that there is generally a lack of subcutaneous fat, which favors escape of heat from the more vital tissues of the body, the normally low production of heat by the organism itself, and the failure to increase this production by shivering, crying and other forms of exercise when the environmental temperature falls below that optimal for the child. Furthermore, the sweat glands do not function as efficiently as they do in the fully developed or "mature" new-born infant, and sometimes they do not act at all.

In view of these environmental problems, the department of pediatrics at the Harvard Medical School has been engaged for several years in attempting to improve atmospheric conditions in hospital nurseries for premature infants and in observing the effects on the growth and development of the young. Blackfan and his associates,³ who have been responsible for this laborious undertaking, have not been indifferent to the factors other than immediate environment that are involved in the successful rearing of the premature infant. They confess at the outset that it depends primarily on four basic principles: (a) stabilization of body temperature, (b) adequate and proper nutriment, (c) prophylaxis against infection and (d) intelligent nursing and medical care. The stabilization of body temperature through accurate control of environmental conditions has been least adequately dealt with.

A special part of the November 1933 issue of the *American Journal of Diseases of Children* was devoted to detailed, technical descriptions of the "air conditioned" nursery rooms at the Infants' Hospital in Boston, where the investigations have continued for seven years. In order to reduce to a minimum those influences which would interfere with the drawing of valid conclusions, special consideration was given to keeping uniform such variables as type of subject, hygiene and clothing, nutriment, and medical and nursing care. For the purpose of securing data with which to contrast the results of the study in the conditioned nurseries, an analysis was made of the hospital records of infants treated over a period of three years in the old unconditioned nursery, before the installation of

the air conditioning apparatus. Humidity has proved to be a significant feature in lowering mortality and in promoting growth. The humidity best suited to stabilizing the body temperature of premature infants appears to be about 65 per cent, with a temperature ranging from 75 to 100 F, depending to some extent on the general constitutional state of the infant and the body weight. A humidity of 30 per cent induced instability of body temperature and other untoward effects, often leading to serious consequences. The body temperature of the premature infant can be controlled much more regularly in rooms in which the temperature, humidity and ventilation rate are adequately managed than in rooms in which these physical factors are allowed to fluctuate.

A surprising outcome relates to the alimentary functions. Air conditions in general and low humidity in particular exerted a conspicuous influence in initiating symptoms referable to the digestive tract. The incidence, as estimated according to an arbitrary index, was at a minimum when the humidity was high and at a maximum when humidity was low. The Harvard studies show that when premature infants live in an environment of low humidity, particularly for a week or more at a time, clinical manifestations of disturbed bodily function are prone to develop, whereas in a relatively high humidity the incidence, severity and duration of the concomitant symptoms are reduced. Furthermore, air conditioning with high humidity notably reduced the mortality from infections, a frequent cause of death in the past. According to Blackfan, the body weight is the most important single criterion for judging the environmental requirements of premature infants. This index has been found to be more reliable than the estimated fetal age, chronological age or body length. From his studies Blackfan modestly concludes that the importance of optimal temperature, humidity and ventilation conditions in the growth and development of premature infants is demonstrable. The research is destined to affect profoundly the future management of the premature infant.

THE HUMORAL THEORY OF NERVOUS FUNCTION

The humoral theory of nervous function owes its inception largely to the ingenious investigations of the pharmacologist Prof. Otto Loewi of Graz. In 1921 he reported his conclusion that the stimulation of autonomic nerves leads to the liberation of definite chemical substances. He noted that, when the vagus nerve that supplies branches to the cardiac tissue is stimulated so that the heart stops, the fluid in the latter acquires the surprising property, when introduced into another heart, of producing typical vagal effects, that is, heart slowing or standstill. On the other hand, when the heart is stimulated under comparable conditions through

² Talbot, F. B., Sisson, W. R., Moriarty, Margaret E. and Dalrymple, Alice J. The Basal Metabolism of Prematurity. III. Metabolism Findings in Twenty One Premature Infants. *Am. J. Dis. Child.* 26: 29 (July) 1923. Talbot, F. B., Bates, Velma, Bates, Eleanor and Dalrymple, Alice J. Skin Temperature of Children. *ibid.* 42: 965 (Oct.) 1931.

³ Blackfan, K. D. and Laglou, C. P. The Premature Infant. *Am. J. Dis. Child.* 46: 1175 (Nov.) 1931.

the cardio-accelerator nerves, the fluid becomes endowed with typical accelerating potencies. In other words, when certain structures, such as cardiac muscles, are stimulated by specific nerves, compounds are liberated into the surrounding medium that mimic the usual functions of the nerves involved.¹ A new view in the conception of the mechanism of nerve stimulation—the conception of chemical mediators—has thus come into vogue. Physiologists are at present busily engaged in establishing a firm foundation for this fundamentally important principle. There are fairly well founded surmises as to the nature of the potent excitatory and inhibitory principles. They seem to be related to, if they are not actually identical with, epinephrine and acetylcholine, respectively. These are substances that have at least one characteristic of many known hormones. They act in extremely minute concentrations in the body—in a few parts per million. Recently Gellhorn and Northup² of the College of Medicine of the University of Illinois at Chicago have endeavored to test in a somewhat new way the Loewi theory of the humoral action of nerve stimulation. These investigators devised experiments in which the intestine is perfused with isotonic dextrose and the blood vessels supplying the intestine with Ringer's solution and the perfusion rate kept constant. Under such conditions the absorption of dextrose is regularly altered by stimulation of the autonomic nerves. Administration of acetylcholine and epinephrine also induces comparable effects under suitable conditions. In fact, the outcome is exactly what one might anticipate if relatively large concentrations of acetylcholine and epinephrine are liberated after vagus and sympathetic stimulation, respectively. These results are in favor of the humoral theory of the action of autonomic nerves. Furthermore, they prove that autonomic nerves alter cellular permeability, at any rate, according to Gellhorn and Northup, assuming the validity of the humoral theory of nervous action and taking into account that the preparation used in these experiments consists chiefly of a part of the intestine and the blood vessels and nerves supplying these tissues, the effect of nervous stimulation on sugar absorption must be due to the liberation of chemical substances which alter the permeability of the intestine if present in minute concentrations. With respect to the mechanisms involved, it has been noted that changes in the inorganic ions in the perfusing fluids may alter the permeability and thus affect absorption. For example, according to Gellhorn and Skupa,³ slight changes in the concentration of potassium chloride and calcium chloride in the artificial solutions with which the blood vessels supplying the

intestine are perfused lead to changes in the permeability of the intestinal wall to dextrose. The absorption of dextrose is increased by potassium and decreased by calcium. The effects were observed even with solutions containing only 0.0075 per cent of potassium chloride and 0.001 per cent of calcium chloride. Hence the influence of organic hormones and specific ions may be interrelated in physiologic functions.

UREA AS A FIBRIN SOLVENT

Thirty years ago it was shown by Limbourg and afterward confirmed by Ramsden¹ and others that saturated solutions of urea dissolve fibrin in vitro. Other proteolytic effects of urea were discovered later, such as its solvent action on casein² and its prevention of the precipitation of certain serum proteins.³ The possibility of therapeutic use of urea as a local fibrin solvent, however, has been generally overlooked, pathologic research stressing the possibilities of preventing surgical adhesions by the use of certain proteolytic plant extracts. Menkin's⁴ recent study of the in vivo fibrinolytic action of urea, therefore, offers a suggestion of clinical interest.

Menkin approached the problem of therapeutic fibrinolysis after a series of preliminary studies of the mechanical role of fibrin in local inflammatory reactions. He found, for example, that, within one hour after subcutaneous injection of staphylococci, physiologic encapsulation of the infected area is effective in rabbits, largely as a result of local lymphatic and interstitial fibrin blockade. Foreign proteins, dyes and particulate matter injected in the blocked area are fixed in the local tissues and fail to drain into the tributary lymphatics. As a second preliminary, Menkin reconfirmed the long neglected observation of the solvent effects of urea in vitro. He found, for example, that exudates withdrawn from aleuronat peritonitis (rabbits) are dissolved in about fifteen minutes if mixed with two volumes of 50 per cent urea solutions. Both fibrin and leukocytes are liquefied by this technique. Strips of fibrinous exudate of human origin were also dissolved, though less promptly, if suspended in concentrated urea solutions, control strips showing no tendency toward liquefaction. Added to uncoagulated peritoneal exudate, urea prevents clotting.

Applying these techniques to living animals, Menkin found that from 10 to 15 cc of 30 or 50 per cent urea solution, injected into the peritoneal cavity of a rabbit, prevents local interstitial and lymphatic fibrin blockade from simultaneously injected aleuronat. Subsequently injected graphite particles drain normally to the regional lymph nodes. In untreated control aleuronat peritonitis, the locally injected graphite particles are

1 A discussion of the subject is presented by Cannon W B *Chemical Mediators of Autonomic Nerve Impulses* Science **78** 43 (July 21) 1933

fixed in the peritoneal tissues. Applying similar tests to previously established peritoneal blockade, the Boston pathologists found that a single local urea injection is an effective solvent of this blockade, subsequently injected graphite particles draining normally from this inflamed peritoneum. Local prevention of fibrin formation and local therapeutic resolution of previously established fibrinous blockades are also effective in subcutaneous tissues.

Whether or not concentrated urea solutions would be lytically effective if applied as surgical dressings to ulcerative surfaces, however, has not yet been determined. Nor, as yet, have the presumptive secondary toxic reactions from therapeutic fibrinolysis been studied. Menkin's only reference to toxicity is one sentence: "Out of a large series of experimental animals, a few died several hours after intraperitoneal injection of 50 per cent urea."

Current Comment

THE BACTERICIDAL ACTION OF KETONIC URINE

A somewhat new possibility in the management of pyelitis was inaugurated through the application of the ketogenic diet to control the objectionable bacteria in the urine. The colon bacillus is the most frequent cause of infection of the urinary bladder and pelvis of the kidney. The plan of treatment originated with Helmholtz and his collaborators¹ at the Mayo Clinic. Fuller,² of Queen Charlotte's Hospital, London, has pointed out that, provided a sufficiently intense ketosis can be obtained, the bacteria and pus often disappear from the urine within a few days, even in chronic cases. At first it was thought possible that the increased acidity alone caused the sterilization, but it soon became evident that there was another factor, for Helmholtz and Clark succeeded in producing sterile urines at p_H 5.5 by means of the ketogenic diet in cases in which the use of acidifying salts yielding a urine of p_H 5.0 had been without effect. This was shown also by experiments on the bactericidal properties of the urines in vitro at 37 C. Helmholtz demonstrated that acidity alone, or in combination with 0.5 per cent of acetoacetic acid, was not responsible for the bactericidal effect of ketonic urine and concluded that some other bactericidal substance was present. Dick³ obtained similar results showing that, while normal urine at p_H 5.5 allowed a free outgrowth of *Bacillus coli*, ketonic urines at this reaction were bacteriostatic, that is, they prevented an increase in the numbers of bacteria without necessarily killing them completely. A solution of the problem of the bactericidal or at least the bacteriostatic potency of the urine in ketosis seems to have been reached by Fuller, who observed that in those cases

in which a rapid cure was obtained, the urine had a pronounced bacteriostatic action in vitro and contained a high concentration of acetoacetic acid, but this is inadequate to account for the striking therapeutic effects. The principal factor inhibiting the growth of bacteria in the urine from patients receiving the ketogenic diet is *l*- β -hydroxybutyric acid. The activity of this substance increases in proportion to the acidity of the urine. Acetoacetic acid and acetone, according to Fuller, are much weaker in their action than β -hydroxybutyric acid and, since they are present in ketonic urine to a much smaller extent than the latter acid, they contribute only a small portion of the total activity.

Association News

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast to coast network each Monday afternoon from 4 to 4:15 Central standard time (5 o'clock Eastern standard time, 3 o'clock Mountain standard time and 2 o'clock Pacific standard time). The next three broadcasts will be as follows:

- April 16 Bird with a White Breast W. W. Bauer, M.D.
- April 23 Sanitation Goes Modern W. W. Bauer, M.D.
- April 30 Science Saves Babies Morris Fishbein, M.D.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central standard time. The next three broadcasts will be as follows:

- April 19 More Health Delusions W. W. Bauer, M.D.
- April 26 Million Murdering Death W. W. Bauer, M.D.
- May 3 Facts or Fallacies W. W. Bauer, M.D.

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Thirtieth Annual Meeting held in Chicago Feb. 12 and 13, 1934

(Continued from page 1163)

DR. REGINALD FITZ, Boston, in the Chair

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Importance of Introducing Psychiatry into the General Internship

DR. FRANKLIN G. EBAUGH, Denver. This article appeared in full in THE JOURNAL, March 31, page 982.

DISCUSSION

DR. C. C. BURLINGAME, Hartford, Conn. I believe that the other branches of medicine do not know what is going on in psychiatry today. They think of psychiatrists still as metaphysicians who are dealing with things entirely detached from the other branches of medicine. As a matter of fact, in the present-day psychiatric hospital the best in physical medicine is practiced. When the good general hospitals are as well equipped in mental medicine and psychiatry as the good psychiatric hospitals are equipped in physical medicine, they will both be a good deal further along. In every surgical and medical and pediatric service there are psychiatric problems. It is somebody's job to recognize them. The rather casual way in which the intern in a service in which a suicide occurred took that matter would lead one to believe that every intern is entitled to a certain amount of fundamental knowledge of psychiatry. How are they going to get this training? There are some state hospitals that would be a splendid place to offer psychiatric

1 Helmholtz, H. F. and Clark, A. L. Proc. Staff Meet. Mayo Clin. 605, 609, 1933. Clark, A. L. Bacilluria Under Ketogenic Treatment J. A. M. A. 95, 1710 (May 14), 1932.
2 Fuller, A. T. The Nature of the Bactericidal Substance in the Urine of Patients Receiving a Ketogenic Diet. Biochem. J. 27, 976, 1933.
3 Dick. Proc. Roy. Soc. Med. 26, 227, 1933.

training. But there are some state hospitals where the custodial type of psychiatry still obtains. Modern psychiatry is not synonymous with the care of cases of psychosis or insanity. A large part antedates any frank breakdown. Psychiatry is suffering from its ancestors. They came from poorhouses and jails, instead of coming from medical schools and general hospitals. If we can only forget our ancestry in psychiatry, and think of ourselves in terms of general medicine, surgery and pediatrics, a lot of our old traditions will drop from us. The leadership is going to come from that type of thinking, and it is our responsibility to furnish that leadership through the general internship and from there on.

DR C. W. McPONTRE, Omaha. It seems to me that if it can be instilled in the mind of the intern to begin with that even a thing as simple as a fracture of a leg contains a functional element and if that can be made to permeate the staff of the institution, they will realize the function of the organic. If we are to move forward with this program of mental hygiene and the problem of the psychologic mind, it will be necessary to introduce that thing all along the line. The man will come out impregnated with the idea that he cannot deal adequately with any case if he is not aware of its sociological ramifications.

DR A. S. BRICE, Boston. We have attempted in Boston University to emphasize the functional side all the way through. We have felt that there is something that is to be known as common sense in medicine and we have been trying to develop that in our students. We begin in the first year with the course in anatomy of the nervous system. We proceed in the latter part of the first year with the work in physiology which has a functional bearing on the nervous system. We then go into the second year where the courses in neuropathology and the beginnings of psychiatry are laid down. We next have a course in formal lectures in psychiatry with demonstrations and following that we have the experiment that Dr. Ebaugh has referred to of sending our students to state hospitals for a residency of four weeks. The way we got this was to add four weeks of training to the senior year so that our senior students have thirty-six instead of thirty-two weeks. So far we have had nothing but commendation for the change.

DR E. S. RYANSON, Toronto. At the University of Toronto as the result of the attitude toward psychiatry, it was decided two years ago to make psychology a compulsory study in the second year and there is now a compulsory course of sixty hours, with lectures in psychology, for all medical students. It is obligatory for everybody. It is on the same standing as anatomy and physiology, not a minor subject. When a student has completed that course he has an opportunity in his third year of going into a more restricted class of psychology in a laboratory form of teaching. In the fourth year there is a still further elective course over and above the courses which begin at that time in psychiatry, spoken of as abnormal psychiatry. In the fifth year the men who have taken that course take an elective course in psychiatry itself, along with the clinical course in psychology. As the result, we feel that the students are getting the point of view which Dr. Ebaugh has pointed out. We have fully recognized this point of view of the importance not only of psychiatry but also of psychology in the training of men who are going out into the general practice of medicine, and at the same time are carrying on along with that a more adequate training for men who are thinking of going into psychiatry. This is the only course in which a student can begin to specialize before he graduates. He cannot take an elective in any of the clinical subjects during his undergraduate course other than psychology.

The Incorporation of the Principles of Preventive Medicine in Clinical Teaching

DR WILSON G. SMILLIE, Boston. In the consideration of every disease entity there are three facets which transmit and reflect the brilliance of clinical analysis: diagnosis, treatment and prevention. The student must know all three if he is to secure a true picture of disease as it is related to the social and economic structure of society. The importance of a consideration of this subject at this particular time is patent. While various, almost revolutionary, social changes have been going

on the relationship of the practitioner of medicine to the community has not changed fundamentally during the past fifty years. There is some evidence that the organized medical profession has not been alert to changing public sentiment in regard to medical practice. One bit of evidence is the widening breach of misunderstanding in many parts of the nation between the official health departments and the medical profession. These two groups should have a common interest and should be working toward the same ultimate goal. Their chief difference is in point of view and method of approach. The health officer's primary interest is promotion of the health of the community as a collective unit, the primary interest of the physician is the promotion of the health and welfare of the individuals of that unit.

In recent years, official health departments have established immunization clinics for smallpox, typhoid, scarlet fever, measles and tuberculosis. Diagnostic and treatment clinics have been established for tuberculosis and for venereal disease, as well as child hygiene clinics, well baby clinics, dental clinics, tonsil and adenoid clinics, eye clinics and clinics for periodic physical examinations. All these essentially clinical activities are, in theory at least, the province of the private practitioner, rather than the health department. It is generally agreed, of course, that these services should be rendered by public or quasipublic organizations for those in the community who are too poor to pay for these necessary services. But then these services become a matter of public welfare, rather than a public health function. The intelligent health officer realizes his position, and will I believe turn these clinical activities back to the physicians as rapidly as they will assume responsibility for them, but he must have due assurance that the work will be carried out speedily and efficiently, and at reasonable cost.

I feel that I state the convictions of the intelligent, foresighted health officials in the proposition that the clinical aspects of preventive medicine should be the function of the private practitioners of the community. The Commission on Medical Education 1930 stresses this feeling, as follows:

Emphasis must be kept constantly upon the fact that only through a sufficient number of properly trained physicians can a community expect to meet its responsibility for the care and prevention of illness and the protection of health. There is no substitute for this essential feature. The Commission on Medical Education states, further: "Present methods of [medical] training in some places are those of a generation ago. The present curriculum in some schools are hampered by a largely useless burden of traditional subject matter and ought to be reorganized. There should be a diffusion throughout the preparation of physicians and especially the clinical department, of the social and preventive aspects of modern medicine. The medical graduate unfamiliar with the newer conditions of practice is at a great disadvantage."

At Harvard University, in addition to formal courses the student absorbs the preventive point of view through unconscious practice of it. The health service for the students is organized on a base similar to a health department of a community. There is a small faculty committee which has supervision of the environmental sanitation of the school, the recreational facilities of the students and the preventive and clinical activities that are planned for the direct benefit of the student body. Each student is given a complete annual physical examination, and facilities are provided for the correction of any defects that may be discovered. The upper classmen examine one another under the supervision of Dr. Fitz. Special attention is directed to the early diagnosis of pulmonary tuberculosis. Each first year student is given a Mantoux test and roentgen examination of the chest on entrance to the school. The same procedures are carried out with each fourth year student as he leaves the school to begin his internship. Each student is given an opportunity to perform and interpret the various specific immunity tests and immunization procedures, the Shick test, the Pirquet and Mantoux tests, the Dick test, smallpox, diphtheria and typhoid immunization, the use of convalescent serum in measles and scarlet fever, and so on.

I hope that I have not given the impression that we believe that the methods we have employed in training our own students in preventive medicine are highly satisfactory to us.

This is far from the case. I can only justify myself in presenting our own methods by returning to the final report of the Commission on Medical Education. It says "The training of students adequately to meet the new philosophy of medical responsibility can only be brought about through a shift in the interests and the point of view of those in charge of medical education who must be convinced of the vital importance of these new influences. This cannot be brought about merely by adding new courses or supplementing existing efforts to call attention to these problems, but only by the awakening of an interest and a stimulation of a fresh viewpoint in the faculties."

DISCUSSION

DR C SIDNEY BURWELL, Nashville, Tenn. If the desirability of infiltrating clinical teaching with the principles of preventive medicine is granted, how are clinical teachers to do it? I am not a strong advocate of setting aside exercises and labeling them "preventive medicine." I prefer to utilize in the practice of medicine the principles of preventive medicine. This type of program may be emphasized in various ways, most of them obvious, but because I have been asked to mention them, here they are: 1 The care of patients with infectious disease in the teaching hospital should be an example of methods of isolation. The care of patients with infectious or other diseases with public health relationships in the hospital or teaching clinics should be examples of cooperation with local health authorities. 2 The students health service should be a demonstration of the point of view and methods of preventive medicine. 3 Routines, such as the history outlines in the hospital, should give due emphasis to environmental factors such as occupation, diet, exposure to infection, and the various prophylactic procedures such as vaccination. 4 To demonstrate the management of disease problems usually requires some method of following up patients after they have left the hospital. In the weekly medical clinic for the third and fourth year classes, periodic "round ups" are held, at which patients previously seen are reviewed. The clinical clerks discuss not only the evolution of the disease process and the influence of treatment but particularly the social implications and public health relationships. 5 Joint teaching clinics in which representatives from the department of preventive medicine may join with the clinical teachers constitute another example of that cooperation between the departments of preventive medicine and the clinical departments. The thing which I believe to be very important is to set in the medical service of the university hospital an example of the practice of preventive medicine and to exhibit an enlightened view with regard to the position of preventive methods in modern medicine. These observations apply as well to the teaching of interns as to the teaching of undergraduate students.

DR ALLEN GREGG, New York. The effectiveness of the public health worker of preventive medicine is directly related to the thoroughness of knowledge that exists about disease. If one goes over the fields in which public health has been particularly successful in various countries, it will be found that prevention of disease has been most effective in those instances in which the etiology of the disease and its handling, its management, are most clearly known. If a physician really knows a disease, knows its exact etiology, there is not much excuse for waiting until the disease has established itself and then being called in. I do not have very brilliant hopes at present of what can be done in the way of preventive medicine in diseases about which relatively little is known. Isn't it better to leave those diseases to the care of those who are still students of them, who are willing to do what they can but not to assume a rather magistral attitude that the preventive position is the only one that can be taken? The real axis around which this discussion revolves seem to me to be a thorough knowledge of disease. It is in direct proportion to our thorough knowledge of disease that the public health man will be effective in his measures against it. For the diseases for whose ignorance we are not to be held entirely responsible the better attitude is to say that we do not know our way completely but will do the best we can. Let the people choose their physicians to take care of them in these diseases in which every one is still relatively speaking, in the dark and save the position

of preventive medicine from criticism. I have seen many examples in many countries of extreme fervor to get something done from the public health angle, being done on a basis of knowledge which experience showed to be inadequate, and the upshot of all of that is a certain amount of discredit. Honestly, do we know that what we advocate as a preventive measure is actually sufficient, or are we simply eager to have as much done as possible and willing to pontificate beyond our actual knowledge? It is precisely in relation to the accumulation of solid, provable, indisputable knowledge about diseases that the field will be opened up to a kind of preventive attitude against which no one will take exception.

The Function of the Physician in Public Health Education

DR W W BAUER, Chicago. The medical activity of today, looking toward instruction of the public, is merely a reawakening and not an initial incursion into a new field. The doctor has been a health educator ever since there were doctors, at least until the time when changes in medical practice began to crowd the family doctor out of the picture in favor of the specialist. The family doctor felt it his duty to instruct his patients about such matters as smallpox, vaccination and other necessary steps to preserve their health. His relationship was informal but effective. Even in the face of official endorsement of the periodic health examination by a number of organizations there are many who hold that the less formal but more intimate relations between the family doctor and his patients were more desirable and effective than are the practices that are advocated today.

The public has awakened to a keen curiosity about its health. This curiosity is mainly misdirected. There is no lack of interested persons busily engaged in misleading the public interest in health for private profit. The influences apparent today in magazines, on billboards, in newspapers and by way of the radio, constitute, in my judgment the plainest handwriting that has ever been written admonishing the physician that he must function as a health educator if he is to save the public from the fruits of its own folly and if he is to retain or regain leadership among guardians of the health of the people.

There has grown up a group who call themselves health educators. It includes doctors who find themselves better fitted for participation in group endeavors, teachers, social workers and public-spirited individuals with a genuine urge for service. It attracts philanthropists with more money than judgment and it offers a rare opportunity for activity to busybodies who have no genuine occupation. It is the least qualified of these groups who make the most noise.

One great weakness of mass educational movements is that they tend to become blatant for the sake of attracting attention. Mass movements in health education, as in politics or any other field, tend to attract to themselves the cranks and those with an ax to grind. There are physicians who consider that all educational activities should be abandoned because misunderstanding may arise and neuroathenic tendencies may be favored by free dissemination of information. The profits from well conceived educational activities include a better appreciation of medical science, better understanding of difficulties involved in diagnosis and treatment, more skepticism about quackery and charlatanism, greater and more constructive interest in medical progress and scientific research, and livelier appreciation of hygiene, diet and medical supervision in health. The doctor may properly display an unselfish interest in furthering the accumulation of these profits because they are in the interests of the public health.

The material that is being offered the public by the medical profession is educational. It is not primarily in the interest of the doctor but in the interest of the patient. There is no more reason why the medical profession should pay newspapers and radio for the dissemination of health information than there is for mathematicians to pay for the teaching of arithmetic in the public schools. The radio is being used extensively by organized medicine. The American Medical Association broadcasts weekly over a coast to coast network. At least seventy state district and county medical societies broadcast on regular weekly schedules with material furnished by the Bureau of

Health and Public Instruction of the American Medical Association, and others are developing their own material. In addition, there are medical societies which broadcast occasionally. It may be assumed that from 125 to 150 county medical societies are using the radio, so that there is scarcely a radio set which is not within range of an educational program sponsored by organized medicine.

News releases have been extensively employed by public health organizations. Voluntary health agencies have also used the newspaper release technique. So also have medical societies in a number of states. Some of these services are gratis to the press, but there is at least one which is sold to newspapers. County medical societies are employing news releases in a number of instances, getting their material from the monthly clip-sheet of *Hygeia*, the health magazine, which is available to any component or constituent society on request. Speakers' bureaus are commonly organized by state medical societies and in counties that contain larger cities. In the more remote areas where there is no great supply of speakers for meetings of lay groups, medical societies could render a definite service by organizing speakers' bureaus and letting it be known that their members will address lay groups on subjects of interest to their health. It seems reasonable to suggest that state and county medical societies might properly take an interest in seeing that the right kind of reading is available to lay inquirers about health topics. All that should be attempted is to be sure that medical literature of a kind which meets with the approval of the profession is not denied a fair place among the books purchased in a community library. To the extent that the play, the exhibit and the pagerium can be used without sacrificing dignity, they must be utilized.

Medical activity in health education is on the increase. To the extent that the resources of the Bureau of Health and Public Instruction permit, we are happy to cooperate with the local medical profession in furthering public instruction for better health.

DISCUSSION

DR H. S. CUMMINS, Washington, D. C. I am inclined to think that from a quantitative standpoint there is entirely too much education on medical matters going on over the radio. If the quality could be improved and the quantity decreased it would help. The public health administrator realizes that there are certain things which public health authorities must do for the body politic, that there are certain things which the physician must do for the public that there are certain things which the citizenship must do for itself and that there are certain things which can be done only through the cooperation of the citizen, the public health authorities and the physicians. If the general public is not informed as to the need for personal and public hygiene and sanitation, it is extremely difficult to secure interest in these matters. These facts have made it increasingly apparent that, unless public health education is brought to the general public, the greatest good cannot be attained. As a result there has been devoted more and more time to public health education among the general population. In some instances this has been carried to a high degree of excellence. In others the results have not been so satisfactory. During a serious epidemic, when everybody wants to know what steps must be taken to stamp out the scourge, the opportunity for public health education is easy. The good obtained in this way is likely to be temporary, it cannot be relied on to produce lasting results. It has been wisely said that "a mere increase in knowledge is not enough to safeguard health and prevent disease, the knowledge must be understood, accepted, and practiced by the people." Public health work can never be efficient until the general public understands the end in view, for what the public does not understand, it will carry on irregularly, inadequately or not at all. It has long been realized that the public health of a community depends on the personal health of the individuals composing that community. The practicing physician is the one who comes in the most intimate contact with the personal health of the community and to him is given the unusual opportunity for effective public health education. Often physicians do not take full advantage of the opportunity afforded them for health education in their own private practice. The Public Health Service is in receipt of

hundreds of letters asking questions that give evidence that the family physician was not interrogated or that if the query was presented to him he gave a hurried or evasive reply. It is felt that the physician in active practice should endeavor to take the time to answer as well as he can the various questions that arise regarding the illness of individuals. A sense of personal responsibility toward the public health is one of the qualities of individual citizenship which must be developed and fostered by every means at our command. It is this sense of personal initiative and responsibility and the ability of the individual to think and act for himself which is one of the basic elements of greatness of the American nation. To give information on any subject to every one in a community is a tremendous task and one that can never be finished. The magnitude of such a task should be a challenge to the physicians and public health administrators of the nation to develop a plan whereby each community may feel a sense of responsibility for the important task of health education. There must be some leadership in health education in each community, and it would appear logical that the physicians should combine forces with the public health authorities of the several communities to take the lead in this important work. It is important today to offset the subversive influence of the increasing amount of questionable and actually harmful so-called health education, and practicing physicians and official health organizations should ally themselves in their efforts to provide the best and the soundest knowledge that can be given in health education. It is desired to emphasize particularly one point brought out and that is the importance of seeing that libraries are provided with the proper material dealing with health information. The public health education that has been carried on so far has been the means of stimulating great interest of the general public in health matters. This interest should be met by providing suitable books and reference material on these subjects, which will give the information desired in the proper form.

The Teaching of Industrial Hygiene

DR LEIFRITT D. BRISTOL, New York. This paper was published in full in THE JOURNAL, March 31, page 990.

DISCUSSION

DR EDWARD C. HOLMQUIST, Chicago. I think that the teaching of this subject is important in the medical field because it should be in the hands of medical people to carry out industrial hygiene. Another is a point of view of the experience. Dr Bristol's experience has been in medical and public health work. Mine has been more in the treatment of these situations. With his program of industrial hygiene I notice that he places the treatment of injuries in occupational disease down as a poor third. I would put the treatment of injuries in occupational disease and the treatment of occupational disease a little higher on the list. I should like to see it close in rank and position. I think that its treatment is important.

DR REICHAARD FITZ, Boston. I wish that Dr Bristol had spoken about the history of industrial hygiene in this country because being a Bostonian, I think that it started there. Two hundred and ten years ago, rum was distilled through lead pipe and it was discovered that people had belly ache and wrist drop and weakness of the ankles from drinking it. A law was passed that henceforward it should be forbidden to distill it through lead pipes or worms. I think that was the first law with regard to that in this country. I think that being a physician to the medical students of Harvard College makes me an industrial hygienist. I think those boys are engaged in an industry, and I think it is in the medical school that they have a chance to learn something about industrial hygiene. Dr Bristol's figures interested me because the one illness we have more than anything else is the same as his, the common cold. The thing I should like to have him work out would be some method by which we could see if he and those of us who are struggling to teach in medical schools are not dealing with the same problem. Everything he has to say, I think deals with the medical student's health, preventing colds, preventing tuberculosis. We have epidemics interfering with their work as students, entirely analogous to what he sees in the industry he works for.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION PUBLIC HEALTH ETC.)

ALABAMA

Lectureship in Honor of Physician—The Gaston J Greil Memorial Lecture was recently created by the Montgomery County Medical Society in honor of the late Dr Greil, a past president of the society. Dr Marvin F Haygood, superintendent of the State Tuberculosis Sanatorium at Alto, delivered the first lecture, March 22, on tuberculosis. Dr Greil, who died in 1932, established the old Anti-Tuberculosis League in 1908, according to the Montgomery *Advertiser*.

CALIFORNIA

Dr Dunshee Named State Health Officer—Dr Jay D Dunshee, health officer of Pasadena, has been appointed state health director, succeeding Dr Giles S Porter, effective April 1, newspapers announced. Dr Dunshee, who is 52 years of age, graduated at the State University of Iowa College of Medicine in 1908. He has been health officer of Pasadena since 1929 and was recently elected president of the Southern California Health Association for 1934. Prior to his appointment in the Pasadena health department, Dr Dunshee was for seven years director of the division of child hygiene of the Los Angeles Health Department. Charles W Arthur, bacteriologist, will serve as acting health officer of Pasadena.

Society News—Dr Nathaniel Austin Cary, Oakland, among others, addressed the Alameda County Medical Association, March 19, on the postfebrile care of the poliomyelitis patient.—Dr Langley Porter, San Francisco, spoke before the San Joaquin County Medical Society, March 1, on 'The University of California Medical School and the Practitioner'.—The Solano County Medical Society was addressed in Vallejo, March 13, by Drs Sylvan L Haas and Hans Lisser, San Francisco, on 'Surgical Aspects of Poliomyelitis' and 'Endocrine Disturbances of the Pituitary Gland,' respectively.—Speakers before the Medical Society of Veterans Administration Facility, Palo Alto, March 21, were Drs William Kerr and William E Carter, San Francisco, on 'Circulation and the Conduction System of the Heart' and 'The University Medical School and the Practitioner of Medicine,' respectively. The physicians are associated with the University of California School of Medicine and Hospital, respectively.—At a meeting of the Galen Club in San Diego, March 5, Drs William C Cooke and John C Schlappi discussed 'Etiology and Prevention of Heart Disease' and 'Management of Heart Failure,' respectively.

DISTRICT OF COLUMBIA

Medical Bills in Congress—Bills Introduced S 3259 introduced by Senator King, Utah, proposes to abolish the office of coroner and to establish the office of medical examiner for the District of Columbia. H R 8935, introduced (by request) by Representative Norton, New Jersey, provides for the prevention of blindness in infants born in the District of Columbia.

Appointments at Georgetown University—Recent appointments to the faculty of Georgetown University School of Medicine, Washington, include the following:

Dr Laszlo D Detre formerly director of the Hungarian Serum Institute special lecturer in immunology effective February 1.
Dr John R Schenken formerly of the State University of Iowa College of Medicine Iowa City instructor in pathology effective February 5.
Dr Philip Lewis Gray formerly of the University of Texas School of Medicine and recently engaged in private practice associate professor of pharmacology effective February 15.
Dr William F R Phillips formerly of the Medical College of the State of South Carolina visiting professor of anatomy effective February 1.
Joseph L Schwind Ph D formerly of Cornell University College of Medicine New York associate professor of anatomy effective July 1.

FLORIDA

Society News—Dr James Ralston Wells Daytona Beach, among others, spoke before the Volusia County Medical Society February 13 on carcinoma of the breast.—At a meeting of the Dade County Medical Society March 2 the speakers were Drs Arnold H Kegel, Chicago on angina pectoris relieved by total thyroidectomy, and Elmo D French Miami, dermatology with special reference to the new-born.

Bogus Representative of Board of Health—A racket perpetrated by a so-called representative of the state board of health is described in recent newspapers. Visiting rural towns, this man's method is to question residents, obtain specimens and prescribe, for which service he charges a fee. He gives his address at the state board's laboratory in Tampa, but requests his "patients" not to call him there, since he is in the city only long enough to sleep. His day hours are devoted to treating people, he claims. Any one encountering this impostor should communicate with the state board of health.

ILLINOIS

Personal—More than forty physicians gave a dinner party, March 11, to observe the seventy-second birthday of Dr Edward C Zoll, Elmwood. A birthday book was presented to Dr Zoll, containing the names of all those in attendance.

Error in Index—A news item about E H Bernard, who was found guilty of the illegal practice of medicine in February, was indexed in THE JOURNAL April 7, page 2, as follows: "Kuflewski, S J, found guilty." As chief inspector of the Department of Registration and Education of the State of Illinois, Mr Kuflewski reported the case to THE JOURNAL and his name was inadvertently inserted in the index instead of that of the illegal practitioner.

Society News—Dr Edwin W Hirsch, Chicago, addressed the Will-Grundy County Medical Society at Joliet, March 28, on "Treatment of Gonorrhea."—Dr Philip H Kreuscher conducted a clinic for crippled children at Sterling March 29, under the auspices of the Sterling Gyro Club and Whiteside County Medical Society.—Dr Rollin T Woodyatt Chicago, discussed "Water Metabolism and Maintaining the Water Balance" before the Springfield Medical Club, March 20.—At a meeting of the St Joseph County Medical Society, March 21, Dr Thurman B Rice Indianapolis, spoke on 'Local Immunization Including Antivirus and Bacteriophage Therapy'.—Dr Willis D Gatch, Indianapolis, addressed the Randolph County Medical Society, March 12, on 'The Principles of Surgery'.

Chicago

Cancer Meeting—Dr Fielding O Lewis, professor of laryngology, Jefferson Medical College Philadelphia, will be the guest speaker in a symposium on carcinoma of the larynx before the Chicago Medical Society April 18, in the Medical and Dental Arts Building. His subject will be laryngectomy, demonstrated with moving pictures. Other speakers and their subjects will be Drs James T Case and Max Cutler on irradiation, and Samuel Salinger laryngofissure. A dinner and reception will precede the meeting.

Society News—Dr Jack D Kirshbaum among others, spoke before the Chicago Pathological Society, April 9, on 'Intestinal Obstruction by Sequestered Lipoma of the Jejunum'.—Among the speakers before the Chicago Laryngological and Otological Society April 9, was Dr John A Cavanaugh on 'Mucocoele of the Frontal Sinus'.—At a meeting of the Chicago Roentgen Society, April 12, papers were presented by Drs Byrl R Kirklm, Rochester, Minn, and Sidney A Portis, on 'Differential Diagnosis Between Benign and Malignant Ulcerating Lesions of the Stomach' and 'Medical Aspects of Benign and Malignant Lesions of the Stomach respectively'.—At a joint meeting of the Institute of Traumatic Surgery and the Chicago Orthopedic Club, April 13 Drs Dallas B Phemister and Fremont A Chandler spoke on "Primary Shock Produced by Wounds and Operations" and "Problems in the Pathology of the Hip Joint in Children".—Speakers before the Chicago Ophthalmological Society April 16 will include Drs Isidore Finkelman and Samuel Wick, Elgin Ill, on 'Pressure on the Optic Nerve by a Carcinoma of the Maxillary Sinus Extending into the Cranial Cavity'.—The Chicago Society of Allergy will be addressed April 16 by Drs Eugene F Traut on 'Reactions of Nonarthritic and Arthritic Persons to Bacterial Filtrates' and Theodore Cornbleet and Morris A Kaplan on 'Proteose Studies in Eczema'.

INDIANA

Personal—E Mead Johnson, aged 81, president of the Mead Johnson Company in Evansville manufacturers of medical supplies and baby foods, died suddenly, March 2 of heart disease at Miami Beach Fla.—Dr and Mrs Malachi R French, Evansville celebrated their golden wedding anniversary, March 4.—Dr John I Mitchell Salem, has been made health officer for Washington County, succeeding the late Dr Samuel A Roberts.

Rat Eradication Program—Plans were formulated, March 10, for a rat eradication campaign to be carried on in Indiana, according to the state board of health. Members of the state board of health, the Indianapolis Health Department, Purdue University and the U. S. Department of Agriculture met with a representative of the governor's commission to undertake the organization of a systematic campaign.

Dental Meeting—Dr. Morris Fishbein, editor of *THE JOURNAL*, addressed the eighteenth annual meeting of the Isaac Knapp District Dental Society in Fort Wayne, March 27. Other speakers included Glenn J. Pell, DDS, Indianapolis, on "Oral Surgery, Extraction and Impactions for the General Practitioner," and Elbert C. Pendleton, DDS, Chicago, on "Biological Aspects of Denture Retention." Ezra E. Voyles, DDS, president, Indiana State Dental Association, also spoke.

IOWA

Tilton Jailed—Lester J. Tilton, Clinton began serving a term of thirty days in the Scott County jail, March 22, for nonpayment of a fine of \$1,000 imposed in federal court at Des Moines, for violation of the federal Food and Drugs Act (*THE JOURNAL*, Dec. 16, 1933, p. 1974). According to the *Chicago Tribune*, Tilton must sign a prisoner's oath to gain his freedom at the end of a month.

Society News—Dr. Joseph C. Ohlmacher, Vermilion, S. D., addressed the Des Moines Academy of Medicine and Polk County Medical Society, March 27 on "Functional Basis of Certain Kidney Disorders with a Brief Consideration of the More Important Kidney Lesions." Dr. William P. Wherry, Omaha, addressed the section on ophthalmology, April 13, on "Practical Applications of Newer Research in Chronic Sinusitis." Diseases of the respiratory tract were discussed by Drs. Daniel J. Glomset, Joseph B. Priestley and James A. Downing, all of Des Moines before the Hardin County Medical Society in Eldora, March 20. Dr. Solon Marx White, Minneapolis, addressed the Cerro Gordo County Medical Society, March 20, on "Heart Disease Among Elderly People." Dr. Gerald V. Coughlan, Council Bluffs, among others, addressed the Pottawattamie County Medical Society, March 20, on "Management of Prostatic Obstruction."

LOUISIANA

Society News—At a meeting of the Fourth District Medical Society in Shreveport, March 6, the speakers included Drs. William Battle Malone, Memphis, on "Surgical Diseases of the Spleen," and George R. Herrmann, Galveston, Texas, "Peripheral Vascular Diseases." At a recent meeting of the East and West Feliciana Bi-Parish Medical Society, Drs. Oscar W. Bethea and Paul T. Trilbot spoke on physical diagnosis and arthritis, respectively. Speakers before the Claiborne Parish Medical Society, February 8, were Drs. J. W. Cox on the control of cancer, Carl O. Wolff, Haynesville, cancer of the breast and uterus, and Clifford P. Rutledge, Shreveport, x-rays and radium in the treatment of cancer. Speakers before the Orleans Parish Medical Society, February 26, were Drs. Allan C. Eustis on "Physiologic Preventive Medicine," Joseph Hume, "A Consideration of Urinary Stone" and James W. Warren, "Complete Prolapse of the Rectum, Treated by Office Methods." Dr. Everett D. Plass, Iowa City, addressed a joint meeting of the New Orleans Gynecological and Obstetrical Society and the Orleans Parish Medical Society, February 19, on "Gestational Polyneuritis."

MASSACHUSETTS

Rockefeller Gift Provides Psychiatric Clinic—The establishment and maintenance of a psychiatric unit at the Massachusetts General Hospital, Boston, is now in prospect through a recent gift of \$80,000 by the Rockefeller Foundation. Of this sum, \$42,000 will go to Harvard Medical School for psychiatric work and the remainder will be available for the establishment of the clinic, the construction of which will begin in September. Dr. Stanley Cobb, Bullard professor of neuropathology at Harvard, will direct the project. Mental diseases in the early stages, as they appear in medical wards and in outpatient departments, will be studied in the new unit, and a small ward will be available for special treatment of incipient cases. Close cooperation will be established with McLean Hospital, Belmont, which has recently been reorganized, for the treatment of the more difficult cases. Simultaneously with this announcement comes the report of the appointment of Dr. Tracy Jackson Putnam as the first incumbent of a newly created chair of neurology at Harvard Medical School. He has also been appointed by the trustees of the Boston City

Hospital to take charge of the laboratories of its neurologic unit. A recent development at the hospital, this unit includes two wards for neurologic and neurosurgical patients and laboratories for the careful study of these patients and for research. Dr. Putnam graduated from Harvard in 1920. According to the *New England Journal of Medicine*, these changes are part of a coordinated plan in the medical school to bring into the department of diseases of the nervous system opportunities to study all kinds of mental and organic nervous diseases. Investigators from Harvard have been engaged in research at the Boston Psychopathic Hospital under the direction of Dr. Charles Macfie Campbell, professor of psychiatry, and Dr. Harry C. Solomon, assistant professor of psychiatry.

MINNESOTA

Illegal Practitioner Fined—Mrs. Christine Nelson, Minneapolis, pleaded guilty to a charge of practicing medicine without a license, February 26, and was sentenced to pay a fine of \$250 or serve six months in the Minneapolis workhouse. The sentence was stayed for one year on condition that Mrs. Nelson refrain from practicing medicine. Mrs. Nelson had been treating a Minneapolis woman for cancer of the breast for about two years and a half, during which time she had collected \$310, it is reported. The treatment consisted of the application of a salve followed by the application of a flax seed poultice causing a sloughing of the involved area. The patient's condition became worse and it was necessary to call in a physician, who operated in November 1933. On her card Mrs. Nelson identifies herself as a graduate of Professor Yuell's Swedish massage system and as a "cancer specialist—at your own risk."

MISSOURI

Personal—Dr. George C. Bellows has resigned as chairman of the public health and welfare committee of the chamber of commerce of Kansas City, after twelve years' service. Dr. Edward H. Skinner was named to succeed him. Dr. John D. Hayward was presented with a silver loving cup by the St. Louis County Medical Society, January 10, in appreciation of his services as president of the society in 1933. Dr. Robert T. Gibbs, Mexico, recently completed fifty years in the practice of medicine. Dr. William O. Hawkins, Roanoke, recently observed the completion of his fiftieth year in the practice of medicine.

The Press and Medical Achievements—The use of the names of members of the St. Louis Medical Society in connection with news items "describing the art of manipulation and instrumentation of certain given cases" is disapproved by the ethics committee, according to the society's bulletin. The right of the public to information and achievements of new developments by local members of the profession is acknowledged by the committee, but, it points out, "the publication of the event and the achievement do not carry the ethical justification for iteration on the part of certain members wherein the publication carries their name or names."

Society News—A symposium on allergy constituted the meeting of the St. Louis Medical Society, March 27, with Jacques J. Bronfenbrenner, Drs. French K. Hansel, Charles H. Liermann, Lee P. Gay and Charles M. Stroud as the speakers. Speakers before the Jackson County Medical Society, Kansas City, March 20, were Drs. James B. Weaver and Ellis W. Wilhelmy on "The Narrowed Lumbosacral Disk as Etiologic Factor in Sciatica," and "Achyilia Gastrica," respectively. Dr. John W. Shuman, Los Angeles, discussed "Thyroidism before the society, April 10, and Dr. Thurman B. Rice, Indianapolis, "The Private Physician in Public Health." Dr. Julius Frischer, Kansas City, was guest speaker before the Newton County Medical Society at Neosho, March 19, on "Transurethral Electrosurgery of the Prostate." At the clinical meeting of the St. Louis Pediatric Society, April 6, Dr. Stanley L. Harrison, among others, discussed "Paroxysmal Tachycardia in a Three Months Old Infant, with Review of Previous Cases."

MONTANA

Society News—Dr. Laurence G. Dunlap, Anaconda, was reelected president of the Montana Academy of Ophthalmology and Oto-Laryngology at its midwinter section meeting in Missoula, February 12, and Dr. Ashley W. Morse, Butte, reelected secretary. The society will entertain the Pacific Coast Oto-Ophthalmological Society at its meeting in Butte, July 16-18, and the Western Ophthalmological Society at its convention in Butte, July 19. Dr. Roderic P. O'Connor, San Francisco, demonstrated his muscle operation at clinics in Butte and Anaconda, February 22.

NEVADA

Annual Registration Due May 1—All practitioners of medicine and surgery holding licenses to practice in Nevada are required by law to be registered annually on or before May 1, with the treasurer of the Board of Medical Examiners, and at that time to pay a fee of \$2. Failure to pay operates to forfeit a licensee's right to practice medicine and his license to practice can be reinstated thereafter only on the payment of a \$10 penalty.

NEW JERSEY

Bill Passed—S 136 has passed the senate, proposing to grant to physicians treating persons injured by the fault of other persons liens on all claims, rights of action, judgments, compromises or settlements accruing to the injured persons by reason of their injuries.

Society News—Dr Stanley L. Wang, New York, addressed the Bergen County Medical Society, Hackensack, March 13, on urinary tuberculosis—Dr Isidor S. Raydin, Philadelphia, addressed the Camden County Medical Society, Camden, March 6, on "End-Results of Biliary Tract Disease"—Dr John J. Moorhead, New York, was the speaker before the Atlantic County Medical Society, Atlantic City, March 9, on "Essentials of Traumatic Surgery"—Dr Dean Lewis, Baltimore, President, American Medical Association addressed the Essex County Medical Society, Newark, March 8.

NEW YORK

Dr William Pierce Honored—The Medical Society of the County of Montgomery gave a banquet, February 14, at the Elks Club, Amsterdam, in honor of Dr William R. Pierce, secretary of the society since 1904 who has completed fifty years in the practice of medicine. Dr Horace M. Hicks was master of ceremonies, formal addresses were made by Drs Orrin S. Wightman and Daniel Philip MacGuire, New York, and many persons paid tribute to Dr Pierce in short speeches. Dr Pierce was graduated from the University of Pennsylvania School of Medicine in 1884.

Bills Introduced—S 1710 and A 2170 propose to permit corporations to be organized under the membership corporations laws of the state to establish, maintain and operate a nonprofit hospital service plan. Such corporations are to be exempt from the insurance laws of the state. S 1724, to amend the medical practice act, proposes to make it unlawful for any one other than a licensed physician to conduct, direct, supervise or control the work or reports of a clinical laboratory. The bill defines a "clinical laboratory" as a laboratory in which tests are made on individual persons, their secretions, excretions, blood and tissues to aid in the diagnosis, prognosis, or treatment of the individual's physical or mental state or states. A 2118, to amend those provisions of the medical practice act relating to osteopathy, proposes (1) to refer to osteopaths as "osteopathic physicians" and (2) to provide that a license to practice osteopathy shall not entitle the holder thereof to perform any surgical operation involving an incision opening a natural body cavity, or any surgical operation for the removal of cancer or other tumor for the amputation of an extremity or an appendage, or for the removal of any gland or organ or part thereof, of the human body. Such a license shall permit the holder to use those agencies incidental to the care of the diseases included in the examinations of the board of medical examiners, but this shall not be interpreted as authorizing the use of internal medication for the cure of disease. S 1677 and A 2165 to amend the education law relative to credentials propose to make it unlawful for any person to attempt to obtain by fraudulent means any certificate of registration or any diploma, certificate or other instrument, or duplicate thereof, purporting to confer any literary, scientific, professional or other degree. A 2164 to amend the medical practice act, proposes to make it a ground for the revocation of a license to practice medicine for the holder thereof to be guilty of unprofessional conduct. S 1663 and A 2123 propose to create in the department of mental hygiene a board of psychiatric examiners to consist of the state commissioner of mental hygiene, the head of the department of psychiatry or of neurology and psychiatry of a medical college in the state and a physician selected by the council of the medical society of the state. This board is to license as qualified psychiatrists all applicants who (1) have been licensed to practice medicine for at least five years and have had five years experience in actual practice and (2) have had three years full time practice in the care and treatment of persons suffering from mental diseases or mental defects in an institution providing for such treatment and having accommodations for at least fifty patients or who

have devoted five years immediately prior to their application to a practice confined wholly or substantially to the care and treatment of persons suffering from nervous and mental diseases or mental defects. S 1632 and A 2078, to supplement the workmen's compensation act, propose to require employers to pay compensation and provide medical care and treatment to employees contracting silicosis in the course of their employment.

New York City

Campaign Against Rats—Under the direction of the U. S. Public Health Service, 200 workers furnished by the Civil Works Administration were to begin a forty-five day campaign against rats during the latter part of February, according to the *New York Times*. It was expected that the number would shortly be increased to 1,800 men, who would be armed with 67,000 traps and 2,000 flashlights. They were to hunt the rodents under piers along the waterfront and in lofts, warehouses and abandoned buildings. Dead rats were to be incinerated, but a number were to be saved alive for experimental work in connection with typhus fever and Brill's disease in the government laboratory at Rosebank, Staten Island. The extermination of rats is part of a program for typhus control begun by the U. S. Public Health Service two years ago, it was said.

Personal—A committee headed by Dr Haven Emerson will make a survey of tuberculosis in the city at the request of the department of hospitals—Dr Charles C. Hedges has been appointed superintendent of Roosevelt Hospital—Dr James B. Collip, professor of biochemistry, McGill University, Faculty of Medicine, Montreal, delivered the William Henry Welch Lectures of Mount Sinai Hospital, March 26-27, on "Recent Advances in the Physiology of the Anterior Pituitary Gland"—Dr Robert Abrahams was the guest of honor at a dinner given March 8, by the executive committee of the New York Physicians-Yorkville Medical Society—The fiftieth anniversary of the graduation of Dr Robert J. Carlisle was celebrated at the reunion and smoker of the alumni association of University and Bellevue Hospital Medical College, March 23—Dr Leopold Jaché was the guest of honor at a dinner recently in honor of his twenty-fifth anniversary as radiologist at Mount Sinai Hospital.

University News—A new degree of doctor of medical science for graduate study in medical fields was recently authorized by the trustees of Columbia University. In petitioning the council for the degree, the faculty of medicine pointed out that such a degree was needed to identify competent practitioners in the specialized branches of clinical medicine and to protect the public from inadequately trained persons. Three years' training after the hospital internship and original work in graduate medical studies will be required of candidates for the degree of doctor of medical science, which replaces that of master of science now conferred for similar work—Edgar Allen, Ph.D., professor of anatomy, Yale University School of Medicine, New Haven, Conn., delivered the second of a series of lectures being sponsored by the department of biology, New York University at the New York Academy of Medicine, March 22, on "The Endocrine Control of Menstruation"—Wilbur W. Swingle, Ph.D., Edwin Grant Conklin, professor of biology, Princeton University, Princeton, N. J., delivered the third lecture, April 12 on "Physiological Study of the Adrenal Cortex."

OHIO

Personal—Dr Frederick C. Gunkel, Cincinnati recently completed fifty years of medical practice—Dr Basil B. Brim has been named health commissioner of Toledo, now a part time position—Dr Matthew T. Love, Shelby, recently celebrated the fiftieth anniversary of the beginning of his medical practice—Dr James M. Lantz, Lancaster, has announced his candidacy for election to the House of Representatives—Dr Owen S. Deathridge, clinical director of the Veterans' Administration Facility at Milwaukee since 1927, has been transferred as chief medical officer to the facility at Dayton—Dr Dennis J. Murphy, recently of the staff of the Veterans' Administration Facility at Marion, Ind., became administrative head of the facility at Chillicothe in January, succeeding Dr Frederick R. Sims, who has been transferred to Washington, D. C.—Dr John A. Roach, Alliance celebrated the fiftieth anniversary of his graduation from Western Reserve University School of Medicine February 28.

Society News—The public health committee of the Cleveland Academy of Medicine is giving special attention to the problem of amebiasis and has conferred with a special committee of the Cleveland Hospital Council on the problems of early recognition and measures for preventing spread of the disease. Drs William J. Merle Scott and John J. Morton

Jr., Rochester, N. Y., addressed the academy, March 16 on peripheral arterial disease.—Henry F. Vaughan, Dr. P. H., health commissioner of Detroit, addressed the Toledo Academy of Medicine, March 2, on "Professional Participation in Public Health Work."—The Toledo Pediatric Society was recently organized, with Dr. Lawrence I. Clark as president and Dr. Isadore R. Colm as secretary.—Dr. Joseph H. Baruch, Pittsburgh, addressed a joint meeting of the Insular and Harrison county medical societies in Ulrichsville, March 8 on "The Nutritional Problem of the Diabetic Patient."—Drs. James R. Jarvis, Van Wert, and Lawrence N. Irwin, Ohio City, addressed the Van Wert County Medical Society, Van Wert, March 6, on "The Challenge of Modern Obstetrics."—Dr. William A. Stoutenborough, Columbus, addressed the Champaign County Medical Society, Urbana, March 9, on "Strabismus in Children."—Speakers before the Wood County Medical Society, March 15, were Drs. James B. Rucker, Jr., and Thomas A. Owens, Toledo, on emphysema and Thomas F. Heatley, Toledo, fractures of the skull.—Dr. William H. Bunn, Youngstown, addressed the Columbiana County Medical Society, Lisbon, March 13, on cardiac irregularities and their treatment.—Dr. John H. J. Upham, dean Ohio State University College of Medicine, Columbus and chairman board of trustees American Medical Association, addressed the Summit County Medical Society, Akron, April 3, on "Heart Disease and Heart Failure, the Modern Problem of Middle Life."—Dr. John W. Carmack, Indianapolis, addressed the Montgomery County Medical Society, Dayton, April 6 on "Cooperation of the General Physician and the Otolaryngologist in the Treatment of Nasal Sinus Infection."

PENNSYLVANIA

The Psittacosis Epidemic in Pittsburgh—A committee of the Allegheny County Medical Society appointed to cooperate with the department of health of Pittsburgh in devising measures to stamp out the epidemic of psittacosis to which several deaths have been attributed issued recommendations following a conference with the department, March 28. The recommendations were to be used as a basis for a city ordinance controlling importation and owning of psittacine birds. The committee recommended (1) that all birds of the psittacine family brought into Pittsburgh since January 1 should be destroyed, (2) that all birds of any species that have been housed in the same store as those of the psittacine family since January 1 should be destroyed, (3) that transportation of all birds into the city be prohibited, (4) that owners of birds of the psittacine family be required to register such birds with the health department, and (5) that owners should be required to report immediately to the health department the illness or death of any bird of the psittacine family. The county medical society, March 20 requested the health department to furnish all available information about the epidemic and to provide isolation facilities for segregation and care of patients with the disease. The health department then requested the society to appoint a cooperating committee, which consisted of Drs. I. Hope Alexander, chairman, William W. C. Archibald and Walter F. Donaldson. Dr. Ray P. Moyer, director of health went to Washington, March 23, to confer with the U. S. Public Health Service concerning further measures of control and the reported irregularities in shipment of birds from California. An isolation ward was established at the Municipal Hospital, March 22. Newspapers reported that about fifty cases of the disease had occurred, with ten deaths.

Testimonial Dinner to Dr. Heckel—The annual dinner of the Allegheny County Medical Society was held in honor of Dr. Edward B. Heckel, Pittsburgh, former chairman of the Board of Trustees of the American Medical Association, April 3, at the Hotel Schenley, Pittsburgh, in recognition of his services and leadership. Gordon J. Lang, Ph.D., dean of the Division of the Humanities, University of Chicago, delivered an address entitled "Are Doctors Human?" At the annual meeting of the society in the afternoon Dr. George E. Pfahler, Philadelphia, delivered an address on "Radiologic Treatment and Results in Cancer, with Special Reference to Cancer of the Breast and Mouth," and Dr. Marion A. Blankenhorn, Cleveland, conducted a clinic. Dr. Heckel, who is a native of Pittsburgh, was educated at Allegheny College and at Bellevue Hospital Medical College, New York. He served as president of the county society in 1905, president of the Medical Society of the State of Pennsylvania in 1913-1914 and was chairman of the Board of Trustees of the American Medical Association from 1925 to 1932. In addition he is a former president of the Pittsburgh Academy of Medicine and the Pittsburgh Ophthalmological Society. He was also for many years a member of

the House of Delegates of the American Medical Association. A hand engrossed framed testimonial was presented to him expressing felicitations on his forty-four years of continuous service to the society.

SOUTH CAROLINA

Bill Passed—S. 770 to enact the uniform narcotic drug act, has been passed by the senate and the house.

TENNESSEE

University News—Dr. Alphonse R. Dochez, professor of medicine, Columbia University College of Physicians and Surgeons, New York, delivered the Phi Beta Pi lecture at Vanderbilt University School of Medicine, February 23, on "The Etiology of Acute Infection of the Upper Respiratory Tract."—The Vanderbilt Medical Library has acquired an extensive collection of books and periodicals of historical interest from Dr. George H. Weaver, Chicago. It contains files of some of the earliest medical journals published in the United States, letters and medical prints.—Dr. Elliott P. Joslin, Boston, conducted a clinic on diabetes at the university, February 14 and Dr. Joseph F. McCarthy, New York, a clinic on urology, March 6. Dr. Paul H. Ringer, Asheville, N. C., addressed the students, March 7, on management of tuberculosis.

Personal—Dr. Jesse C. Ellington, who has been on the staff of the U. S. Public Health Service in the Panama Canal Zone since June 1931, has accepted a position as field assistant with the state department of health, it is reported. Dr. Ellington was formerly on the staff of the department.—Dr. Monroe F. Brown, Memphis, has been appointed health officer of Lincoln County.—Dr. Owen F. Agee has been appointed director of a new health unit in Blount County.—Dr. Samuel Denton, Buffalo Valley, was guest of honor at a dinner given by his family and friends, February 22, celebrating his eightieth birthday. Fifty-three persons attended.—The eighth annual Bal four Lecture in Surgery at the University of Toronto Faculty of Medicine was delivered, April 3, by Dr. William D. Haggard, Nashville.

Health at Memphis—Telegraphic reports to the U. S. Department of Commerce from eighty six cities with a total population of 37 million for the week ended March 31 indicate that the highest mortality rate (22) appears for Memphis and that the rate for the group of cities as a whole was 12.4. The mortality rate for Memphis for the corresponding week of 1933 was 14.2 and for the group of cities, 11.3. The annual rate for eighty six cities for the thirteen weeks of 1934 was 12.7 as against a rate of 12.3 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Dr. Frederick E. Marsh addressed the Chattanooga and Hamilton County Medical Society, February 22, on "Medical and Dietary Treatment of Gallbladder Disease."—Dr. James B. E. Neil was the speaker at a meeting of the Knox County Medical Society, Knoxville, January 16 on "Use of High Frequency Current in the Treatment of Prostatic Obstruction."—Drs. Alfred Blalock and Edward H. Barksdale, Nashville, among others, addressed the Hardin Lawrence-Lewis-Perry-Wayne Counties Medical Society at Waynesboro, in January, on "Empyema" and "Increased Frequency of Urination," respectively.—Dr. Byrd S. Rhea, Lebanon, presented a paper on complications of pregnancy before the Wilson County Medical Society, March 8.—Speakers before the medical society of Carroll, Henry and Weakley counties in McKenzie, February 6, were Drs. Cobb Pilcher and Tinsley R. Harrison, Nashville, on early diagnosis of brain tumor and cerebral vascular disease, respectively, and George R. McSwain, Paris, brain tumor.

TEXAS

Diphtheria Immunization in Dallas—Because Dallas has been shown to have the highest diphtheria morbidity and mortality of any city in the United States, the department of school health work recently undertook a survey of immunization in the public schools. The survey was conducted in forty six elementary schools in which 27,094 children were enrolled. Questionnaires were returned by 15,321 parents and the report covered 45,000 children of elementary, preschool and high school ages. During the school session 1932-1933 there were 138 cases of diphtheria among elementary school children with a loss of 1,750 days and 146 children were absent 1,330 days as diphtheria contacts.

Society News—Dr Edward H Skinner, Kansas City, was the guest speaker at a meeting of the Texas Radiological Society, in Waco, January 8, on "Radiologic Practice and Responsibility."—The fifth and sixth districts of the Texas State Medical Association held their second international post-graduate medical assembly in San Antonio, January 17-19. Guest speakers included Drs William Walters and Henry F Helmholtz, Rochester, Minn., Arthur W Proetz Willard Bartlett and George Gellhorn, St Louis, Franklin G Ebrugh, Denver, John A Kolmer, Philadelphia, Joseph Hume New Orleans, Miguel Bustamante, Gabriel Leyva Alarcon, Gustavo Baz and Enrique Martinez Barragan, all of Mexico. Dr Charles P Yeager, Corpus Christi, was elected president.—Drs James T Mills and Thomas H Chervens addressed the Dallas County Medical Society, March 8, on "Reconstructive Surgery of the Head and Neck" and "Forced Drainage of the Cerebrospinal Fluid," respectively and Dr Charles B Sanders led a pathologic conference on amebic dysentery. Drs Albert P D'Errico and Lemuel C McGee addressed the society, March 22, on "Cerebral Injury Sequelae Their Diagnosis and Treatment" and "Cardiospasm," respectively.—Dr Herbert E Hips Marlin, among others, addressed the Falls County Medical Society, January 8, on "Geometry of Fractures."—Dr Roland T Travis, Jacksonville, addressed the Henderson County Medical Society, Athens, January 8, on appendicitis.

GENERAL

Society News—The eastern section of the American Congress of Physical Therapy held a joint session with the New York and Pennsylvania physical therapy societies at the Columbia-Presbyterian Medical Center, New York, April 7. Speakers included Drs William H Schmidt, Philadelphia, on fever therapy, George Miller MacKee New York, physical therapy in dermatology, Leroy W Hubbard, Warm Springs, Ga., and Mount Vernon, N Y, muscle training and reeducation in treatment of poliomyelitis, Max Thorek, Chicago, an electrosurgical method for obliterating the gallbladder. Robert H Kennedy, New York, physical therapy in the treatment of fractures and Earl R Carlson, New York, neurologic aspect and treatment of birth injuries.—Dr Chevalier Jackson, Philadelphia, was elected president of the Pan American Medical Association during the recent congress and Dr Joseph Jordan Eller, New York, director general for five years. Vice presidents were elected from the countries represented and Dr Jose E Lopez-Silvero, Havana, Cuba, executive secretary for three years.

Board of Pediatrics Organized—The American Board of Pediatrics completed its organization at a meeting in January in St Louis, at which the following officers were elected: Drs Borden S Veeder, St Louis president, Henry F Helmholtz Rochester Minn vice president and Charles Anderson Aldrich, Winnetka, Ill, secretary. Other members of the board are Drs Philip Van Ingen New York, Harold C Stuart, Boston Alfred A Walker, Birmingham Wilbur C Davison, Durham N C, Franklin P Gengenbach, Denver and Edward B Shaw San Francisco. Three groups were defined for purposes of certification as follows:

Group I Physicians who have limited their practice to pediatrics for more than ten years may be certified on their records until September, 1936 after that date examination will be required.

Group II Physicians who have limited their practice to pediatrics for from six to ten years must submit evidence of at least one year's hospital training in a recognized pediatric center and of continued work in some pediatric institution or organization. Examination is required in this group.

Group III Graduates of five years standing or less must submit evidence of having completed one of the following forms of training: (a) one year in a general hospital with two years in a pediatric center or three years in a pediatric center. (b) two years service in a pediatric center plus two years practice in pediatrics including continued work in some pediatric activity. (c) one year's service in a general hospital one in a pediatric center plus three years specialized practice of pediatrics including connection with some pediatric activity. Examination is required of all applicants.

The American Board of Pediatrics was founded by the joint action of the American Pediatric Society, the American Academy of Pediatrics and the section on pediatrics of the American Medical Association each of which appoints three members.

Medical Bills in Congress—*Changes in Status* S 822 to permit the use of the mails for the shipment of certain drugs and medicines to cosmetologists and barbers was reached on the Senate calendar, March 29. Senator LaFollette Wisconsin asked that the bill go over to permit him to ascertain from the Department of Agriculture what its attitude is toward the measure. S 2571 has passed the Senate and House authorizing the Secretary of the Interior to arrange with the states and territories for the education medical attention relief of distress and social welfare of Indians. S 2800 the Copeland food

drink, drugs and cosmetics bill, was reached on the Senate calendar, March 29, but Senator Byrnes, South Carolina, objected to its consideration. H R 1766 has passed the House, to provide medical services after retirement on annuity to former employees of the United States disabled by injuries sustained in the performance of their duties. H R 7835, to provide revenue and equalize taxation, has been reported to the Senate, with amendments. One amendment proposed by the Senate committee would impose an excise tax on the first domestic processing of coconut oil, or sesame oil, or palm oil, or palm kernel oil, or sunflower oil, or imported whale oil or imported fish oil, or imported marine animal oil. The excise tax would be applicable to the medicinal oils. *Bills Introduced* H R 8961, introduced by Representative Dingell Michigan, proposes to amend the Reconstruction Finance Corporation Act, as amended, to provide for loans to nonprofit benevolent charitable corporations.

Kober Medalist and Lecturer Selected—Dr John Jacob Abel, professor of pharmacology, Johns Hopkins University School of Medicine Baltimore, will be presented with the Kober Medal of Georgetown University School of Medicine, Washington, D C, at the annual meeting of the Association of American Physicians in Atlantic City, May 1-2. Announcement of the award was made, March 28, at Georgetown, when Dr Walter B Cannon, George Higginson professor of physiology, Harvard Medical School, Boston delivered the annual Kober lecture on "The Story of the Development of Our Ideas of Chemical Mediation of Nerve Impulses." The Kober Foundation of Georgetown sponsors the medal and lecture each year to commemorate the birthday of the late Dr George M Kober, formerly dean of Georgetown University School of Medicine. The medal is presented for high achievement in the field of medical research, but, according to the report, Dr Abel is being recognized for his forty-one years of distinguished service as professor of pharmacology at Johns Hopkins rather than for any particular contribution to science this year. Dr Abel gave the first Kober lecture in 1925. Other honors conferred on Dr Abel include the Research Corporation prize in 1925, the Willard Gibbs medal awarded by the Chicago section of the American Chemical Society in 1926, and the gold medal of the Society of Apothecaries of London, 1928. Dr Abel is known for research on animal tissues and fluids and on the physiologic and therapeutic action of various substances. He is the editor of the *Journal of Pharmacology and Experimental Therapeutics*. He is a member of many scientific societies and a past president of the American Association for the Advancement of Science.

Changes in Status of Licensure—The Massachusetts Board of Registration in Medicine reported the following action:

Dr Dwight F Willis Boston license restored January 25. It had been suspended Sept 28 1933.

The Oregon Board of Medical Examiners reports the following action:

License of Dr Walter R Anderson Portland was revoked at a recent meeting of the board for unprofessional conduct.

The New Jersey State Board of Medical Examiners reports the following revocation:

Irvin W Kirk Millville registration of medical diploma revoked for the practice of illegal operations.

The State Medical Board of the Arkansas Medical Society reports the following:

Dr Peter A Taylor formerly of St Joe and Gould Ark, license revoked Nov 14 1933 because he had been convicted of a crime involving moral turpitude. In June 1930 found guilty and sentenced to serve three years in the Arkansas State Penitentiary for perjury in the Pope County Circuit Court.

The New York State Board of Medical Examiners reports the following action taken at a meeting, February 15:

License of Dr Burdette M Christianson Brooklyn suspended for six months dating from March 15.

The state department of health of West Virginia reports the following action taken at a meeting in March:

License of Dr Frederick A Fitch formerly of Huntington now of Gauleyburg Ky restored with agreement that he would not apply for narcotic permit. The license was revoked in March 1932.

License of Dr Elmhugh H Hale Cedarville revoked for violation of the Harrison Narcotic Act.

CORRECTION

Lines on Chart in Hospital Number—In the chart on page 1005 in THE JOURNAL March 31 each horizontal line represents 15 million population instead of 10 million as stated in the footnote.

March 17, 1934

The Work of the Medical Research Council

Only within the last thirty years has financial provision, private or public, been made on a large scale in Great Britain for medical research. A beginning was made when Lord Iveagh erected and endowed the Lister Institute for laboratory investigations. The benefaction of Sir Otto Beit, which enabled promising young workers to devote themselves to research by means of fellowships, followed. In 1911, when the national health insurance act came into operation an annual rate of 2 cents for every insured person was paid into a fund for medical research. This furnished \$265,000 per annum, for the administration of which a medical research committee was appointed, and the National Institute for Medical Research was established at Hampstead (in London) in 1913. The Great War began in 1914 and diverted the work of the committee from its primary object. After that catastrophe the committee was reconstituted as the Medical Research Council, and the government increased the annual provision to \$625,000 and subsequently to a still greater amount to meet further development. The reconstituted organization took its place beside the Department of Scientific and Industrial Research, which had meanwhile been created. More recently these have been joined by the Agricultural Research Council, thus bringing science to the service of the community in the three main divisions of human affairs. The Medical Research Council consists of such leading men as Sir Charles Sherrington, J. A. Arkwright, Lord Dawson, Prof. F. D. Adrian, Prof. A. E. Boycott, Sir Thomas Lewis, Prof. D. P. D. Wilkie, Prof. H. S. Raper and Prof. Edward Mellanby. The council is able to foster the most effective relations between science and the state. Though supported by the latter, it has full liberty to pursue an independent policy for the advancement of medical knowledge and it can collaborate freely with other organizations. It is not a mere advisory body, but has full control over its funds and appoints its own administrative officers. Its funds comprise not only the government grant but also money from other sources, public or private, placed at its disposal for medical research.

THE CHANGING PROBLEM OF DISEASE

In its recent annual report the council points out that in the twenty years since the establishment of the original committee the problems of medical research have altered. Many diseases have greatly diminished in deadliness. In some cases no cause can be assigned for this, in others the difference is clearly due to improved social conditions, in still others the credit may be given to preventive medicine. There remains an important group in which the change is the direct result of knowledge acquired by recent research, and to this the workers in this country—many aided by the council—have largely contributed. Among the diseases that have almost disappeared, although for no known reason, is chlorosis, which twenty years ago was one of the commonest diseases in young women. Another disease in the disappearing group is epidemic diarrhea among children. Increased sobriety has rendered cirrhosis of the liver a comparatively rare disease. The work of the council has increased the sum total of knowledge of a number of diseases, but chronic arthritis remains as mysterious as ever. "Status lymphaticus" has been shown to have no existence as a definite morbid state. Mackay's work, published by the council two years ago, has awakened the medical profession to the wide incidence of anemia in infants. Witts has greatly

advanced clinical knowledge of macrocytic and microcytic anemias. Laidlaw, Andrenes and Smith have succeeded in conveying human influenza to ferrets and thus bringing it within the experimental field. Two years ago the council appointed a therapeutic trials committee, composed of clinicians and pharmacologists, to make trials of new remedies.

Lead in Canned Sardines

A new form of food contamination with lead has been discovered. The catering firm of Lyons & Co. has its own chemical laboratories, in which routine examinations for metallic impurities are made of foods that have been in contact with solder. In regard to sardines, it was found that 88 per cent of the samples contained less than 20 parts per million of lead but that the remainder yielded larger quantities, in one case 150 parts per million. In the cans no relation could be found between the amount of exposed solder and the lead contamination. But investigation of the process of sardine packing showed that the fish were cooked on metal grills, which were supposed to be made of tinned iron. In some factories, however, they were covered with soft solder. Contact with such grills was found to produce serious contamination with lead.

The Saving of Life in Sunken Submarines

In the house of commons the first lord of the admiralty stated that after exhaustive consideration the admiralty had come to the conclusion that the raising of sunken submarines in time to save life was not feasible and that the only practicable method of saving life was the Davis submerged escape apparatus, which was now fitted to all submarines. For the future it was proposed to rely on this. The United States authorities had reached the same conclusions. Those serving in submarines are all trained in the use of the Davis escape apparatus (described in *THE JOURNAL*, Sept. 5, 1931, p. 715). If men imprisoned in a sunken submarine thought that attempts were going to be made to raise the vessel there would be grave danger that in spite of their training in the escape apparatus they might be tempted to await the result of salvage operations instead of saving themselves by means of the apparatus. The result would be that they would lose the strength necessary for escape. Vessels would at once proceed to the scene of the disaster and a signal would tell the crew in the submarine of their presence to rescue them after they had escaped.

Davidson Black

The death from heart failure at Peiping of Davidson Black, M.D., D.Sc., F.R.S., professor of anatomy at Peiping Medical College and honorary director, Cenozoic Research Laboratory, National Geological Survey of China, is a great loss to science. He was only 49 and was still engaged on researches in connection with the fossil man discovered by him in 1929. When the field work closed at Chou Koutien at the beginning of the winter, besides the remains of *Sinanthropus*, deposits had already yielded bones of baboons which occupied caves in tertiary times and evidences of upper paleolithic culture. Davidson Black was convinced that the surface deposits were only scratched and was looking forward to resumption of excavations next spring. Born in Canada, he was educated at the University of Toronto. From 1909 to 1911 he was instructor in anatomy at Western Reserve University School of Medicine, Cleveland. In 1913 he became assistant professor a post which he resigned to become a captain in the Canadian Army Medical Corps. In 1918 he was appointed professor of neurology and embryology at Peiping Union Medical College. In a tribute in the *Times* Prof. C. Elliot-Smith states that Davidson Black did more for human paleontology than any one else. At the same time his work represented only the beginning of a task that awaits completion.

The Nature of Influenza

The annual report of the Medical Research Council contains an important study of influenza. Working at the Natural Institute of Medical Research, Drs P P Laidlaw, C H Andrews and Wilson Smith succeeded in conveying human influenza to ferrets. Washings from the nasal mucosa of human cases were passed through a filter that was capable of keeping back ordinary bacteria. The resulting filtrate, containing no microscopically visible organisms, was instilled into the nostrils of ferrets. A characteristic feverish and a catarrhal reaction followed and was transmissible by similar means to other ferrets. After recovery, which was usual, the animals were immune to further infection for a period of which the length has not yet been determined. Infection of the ferret occurred only when the material was instilled into the animal's nostrils. Injection by the needle was ineffective. The experiments have also shown a relation between the influenza virus and that found by Shope in America in the epizootic known as hog influenza. Shope found that this virus by itself produced trivial symptoms but that it was associated with a bacillus allied to the bacillus of Pfeiffer. The bacillus was incapable of producing the swine disease in epizootic form. Only when virus and bacillus were allied as primary and secondary invaders was the severe and naturally spreading disease produced. A strain of the hog influenza virus, supplied by Shope, has been found to produce in the ferret a condition indistinguishable from that caused by the virus of influenza. Further, a ferret that recovers from the influenza virus infection with the swine virus is immune to the influenza virus, while recovery from the latter infection produces a substantial, though not complete immunity to the former. It is noteworthy that many years ago the view that influenza is the fertilizer of the soil for the growth of other diseases was put forward. The late Dr Brownlee showed that influenza tends to recur every thirty-three weeks. If this takes place between April and December the complaint is mild but if it takes place between December and April it is much more severe. Perhaps this is due to the fact that the virus prepares the soil for the bacillus of Pfeiffer and for the organisms of pneumonia and other diseases.

PARIS

Feb 28, 1934

Intravenous Injections of Alcohol in Pulmonary Suppurations

Intravenous injections of alcohol in pulmonary suppurations which awakened alarm at first, are being more widely used in France since the technic of the method has been perfected and manifest results have been secured. Before the Societe de medecine des hopitaux de Paris Merle and Gurfinkel reported excellent results secured in three cases of pulmonary suppurations by the use of this method. One case was an acute gangrenous suppuration of the pulmonic type. The two other cases were chronic types of pulmonary suppuration in which the extent and the old nature of the lesions precluded surgical treatment. In these three cases the results of the treatment were such that they leave little doubt as to the therapeutic value of this method. These observations with similar observations previously published justify one in regarding the treatment of acute or chronic pulmonary suppurations with intravenous alcohol as a method of the first order when surgical treatment is not yet indicated when its indications are doubtful or when it is no longer possible. These cases possibly constitute the majority. One is even justified in expecting that a systematic and early use of this method will reduce the number of cases in which it will be necessary to intervene surgically. The harmlessness of this treatment already estab-

lished by various authors, appears absolutely certain to Merle and Gurfinkel. In more than 250 injections they observed no serious untoward incidents, aside from pain symptoms, which are of regular occurrence but usually easily tolerable, and signs of shock—commonly moderate. The authors concluded that this shock could be ascribed to the strongly hemolytic action of the solutions of alcohol in the serum with 45 per cent dextrose or in the artificial serum. This solution has a much less accentuated hemolytic potency, it diminishes sensibly the shock and the sclerosing action on the veins. The optimal dose of this solution appears to be from 40 to 50 cc per injection. But, in order to secure therapeutic results, it appears indispensable to use rather large total doses, thus necessitating for a cure a total quantity of from 200 to 300 cc of 45 per cent alcohol or from 600 to 900 cc of the 33 1/3 per cent solution.

Verification of the Causes of Death

Repeated complaints have been made because of the unreliable nature of French statistics on the causes of death. The Academy of Medicine became aroused and addressed to the minister a resolution demanding that the verification of the causes of death be made with greater care. The minister has sent a letter of instructions to the mayors of all the communes of France. The instructions provide that the mayor must designate an officer to examine the body and determine the true cause of death. He must state also the name of the physician who attended the patient and that of the pharmacist who furnished the medicines. No one imagines that this letter of instructions to the mayors will immediately bring about ideal conditions. In the large cities there is already a well organized service for the verification of the causes of death by specially appointed physicians.

BERLIN

Feb 19, 1934

Emigration of Physicians from Germany in 1933

According to information compiled by Regierungsrat Dornedden of the federal bureau of health, 284 Berlin physicians emigrated in 1933 to some foreign country. The destination given in 117 instances was Palestine, in 25, France, 22, England, 13, Switzerland, 13, Italy or Spain, 11, Austria, Czechoslovakia or Poland, 9, Scandinavia and northeastern Europe, 8, Netherlands and Belgium, 5, southeastern Europe, 1, Luxemburg, and 30, extra-European countries, while the destination of 30 physicians is unknown. In the case of forty other

TABLE 1—Percentage of Emigrating Physicians from Berlin and from the Remainder of Germany

Destination	From Berlin	From the Remainder of Germany
Palestine	46.1%	37.1%
France	9.8%	11.1%
England	8.7%	6.2%
Switzerland	5.1%	8.6%
Italy	3.5%	6.2%
Other European countries	1.0%	22.2%
Extra European countries	11.8%	8.6%
	100.0%	100.0%

physicians who left Berlin in 1933, the post office was unable to ascertain the present abode. Outside of Berlin reports on only 128 emigrating physicians have been received. Of this number seventy had been located in cities of more than 100,000 population so that 86 per cent of the emigrating physicians were from metropolitan centers.

It appears that almost half of the emigrating physicians were under 35 years of age and more than a further third belonged to the 35-44 age group. Whereas 39.9 per cent of the German

medical profession belongs to the age group 45 and above, only 17.5 per cent of the emigrating physicians belonged to this group. The percentage of women physicians among the emigrants was 14.8, whereas the percentage of women in the medical profession in Germany is 6.5. The number of emigrating physicians representing the specialties is shown in table 2.

TABLE 2—*Specialists Among the Emigrating Physicians*

	Distribution of Specialties		
	In Germany as a Whole	Immigrating Male Physicians From Berlin	From Remainder of Germany
General practitioners	63.7%	43.9%	48.7%
Internal medicine	7.6%	20.0%	13.5%
Surgery	5.6%	5.0%	5.4%
Gynecology	3.2%	6.4%	5.4%
Children's diseases	2.2%	6.7%	10.8%
Dermatology and venereal diseases	4.0%	7.1%	4.7%
Diseases of eye, ear, nose and throat	1.0%	3.4%	4.2%
Other specialties	7.0%	6.2%	7.2%
	100.0%	100.0%	100.0%

It is not yet possible to state exactly the number of physicians who emigrated in 1933. This report, however, gives an idea of the importance of the emigration of physicians from Germany, which, up to 1933, had been small.

Diabetes in Enzygotic Twins

Addressing the Berlin Medical Society, Professor Umher pointed out that diabetes is based on a constitutional inferiority of the islands of Langerhans. It is hereditary and causally independent of the environment. Enzygotic twins who have identically the same hereditary characteristics are particularly suitable for the study of hereditary diseases. According to the computations of von Verschuer of the Emperor William Institute for Anthropology there is a twin for every sixty adults, but only about one third of the pairs of twins are enzygotic. The establishment of the fact that twins are enzygotic is best based, according to Verschuer, on external resemblances with respect to features and bodily form, size, habitus, peculiarities of the organs (ears, eyes and nose), hair growth, qualities of character, trends and the like. A precondition is that they are of the same sex. Umher stated that he had observed three such pairs of twins. It was peculiar in all three pairs of twins that the type of diabetes was exceedingly similar in the two twins of each group. For instance, two twin sisters presented a frank diabetes gravis, and one sister who was not treated died early in coma, while the other sister received insulin treatment and survived longer. In another pair of twins there developed in one a mild case of senile diabetes, whereas the other had no glycosuria whatever. Inquiry revealed that the twin with diabetes had been a tavern keeper and a heavy drinker, whereas in the nondiabetic twin only a pathologic blood sugar curve betrayed his pancreatic weakness. These observations on enzygotic twins with diabetic disturbance of metabolism serve Umher as support for his theory that diabetes is a recessive hereditary disease, which is not caused by the environment but is influenced by it only in its mode of appearance.

Restricting the Medical Curriculum

Rust, the Prussian minister for science, art and public instruction, has transmitted to the medical faculties of the Prussian universities a decree of far-reaching importance on the subject of revision of the medical curriculum. The decree takes as its basis a new curriculum that was proposed by a Prussian faculty of medicine, and, in a somewhat modified form, it is already in force at universities outside of Prussia. The curriculum will need to be modified to fit local conditions, hence it is not intended that the proposals shall be binding on all institutions. Rust emphasized that in no case shall the specified number of hours of instruction be exceeded. If for

instance, a one-semester course in a subject is recommended, it will not be permissible for the subject to be presented in two semesters. The lectures in such cases must be revised. The same principle applies to clinics, in which a greater number of hours than is provided for in the decree may not be demanded. In the revised curriculum it must be made plain, the decree states, that not all subjects are of equal importance for training the practicing physician. In the preclinical studies, the instruction hours for the natural sciences must be greatly reduced. The minister expects the professors of chemistry, physics, zoology and botany to present in a separate course of lectures the subject matter for the medical students. If that does not seem possible, special instructors for the delivery of such lectures and the holding of the corresponding tests should be suggested to the Prussian minister of the interior. In the clinical studies the clinics of internal medicine, surgery, gynecology, pediatrics, pathologic anatomy and all other subjects must be curtailed. It is not the task of clinical instruction to train specialists in all branches. The minister requested that the suggested changes be rigorously carried out, and he emphasized that the deans would be held responsible for the execution of the plan in accordance with the instructions issued. In case, in allotting work to the several professors, the hours of instruction assigned are in excess of what the new curriculum provides for, the minister will reduce the number of hours without any special inquiry. The new curriculum goes into effect with the opening of the summer semester 1934.

Incidence of Syphilis in Clinics

At the Munich Medizinische Universitätsklinik, of which Professor von Romberg is director, some 50,000 case histories covering the period 1912-1932 (1918 excepted) were studied statistically. It was found that, twenty years ago almost 9 per cent of the patients had syphilis. During the war and the years following, the number of syphilitic patients rose owing to the increase particularly of latent infections in both sexes and an augmentation of acute syphilis in the men temporarily up to about 11 per cent. Since 1923, however, there has been a decreased incidence, which has gradually become manifest in all types of syphilis. Thus, in 1932 the percentage of syphilitic persons (41 per cent) was far below the status of 1912.

Retrenchments of the Krankenkassen

For the aid of the sick, the expenditures in 1932 of the federally controlled Krankenkassen in the German Reich amounted to 858,000,000 marks (\$326,000,000), or 81 per cent of the total expenditures. The average cost per member was 50.23 marks (\$19.09). Owing to the reduction in receipts resulting from the extensive unemployment, considerable retrenchment in the expenditures for every purpose was necessary. As compared with 1931, the expenditures of the federal Krankenkassen (omitting the federal allowance for family aid which in 1931 amounted to \$1,026,000 and in 1932 to \$304,000) were reduced 29 per cent (aid for the sick 30 per cent, weekly benefits 19 per cent, and administrative costs 17 per cent), while the expenditures for the prevention of illness, health aid and burial benefits suffered the heaviest reductions, namely from 51 to 52 per cent. As to aid for the sick, the expenditures for pocket money and convalescents' benefits were greatly reduced (80 and 74 per cent, respectively). The reductions for the following items were likewise heavy: domiciliary care 42 per cent, aid for household expenses, 44 per cent, sick benefits 40 per cent and care of dependent members of families 46 per cent. The reductions for the following purposes were not so heavy: physicians' fees, 21 per cent, hospital care for members 25 per cent, and spa treatment, 22 per cent. The smallest reductions were for dental care, the expenditures for members having been only 15 per cent, and for family dependents only 14 per cent, lower than in 1931.

VIENNA

(From Our Regular Correspondent)

Feb 12, 1934

Rôle of Tobacco in Gastric Ulcer

At a meeting of the Gesellschaft der Aerzte, Dr R Friedrich of the Chirurgische Klinik discussed the rôle of tobacco in the etiology and postoperative treatment of gastric and duodenal ulcer. The predominance of the disorder in the male sex is striking, and among the men so affected heavy smokers are in the majority. Various researches and experiments make it probable that persons who have a weak stomach, or already have an ulceration, are injured by smoking. The smoking of from five to ten cigarettes a day caused consistently an exacerbation of the symptoms in ulcer patients. Cigars do not seem to cause so much irritation. However, attention must be called to the fact that gastric ulcer is to be regarded as a manifestation of a general nervous predisposition and that duodenal ulcer occurs often in well nourished, full blooded persons, being frequently induced by the ingestion of too strongly seasoned food. Smoking causes a marked increase in the secretion of gastric juice, and exact observations on a large series of patients have convinced Dr Friedrich that patients who have been operated on for ulcer and continue smoking have more frequently pain and discomfort than those patients who discontinue smoking after the operation. He demands that a person operated on for gastric or duodenal ulcer shall give up smoking. It is true that now many women smoke, although statistics do not show an increase of ulcer cases among women. Perhaps the difference lies in the fact that women seldom smoke "on an empty stomach" and commonly smoke fewer and milder cigarettes.

The Physical Bases of Short Wave Therapy

Four weeks ago the Biophysikalische Gesellschaft fur Kurzwellenforschung was founded in Vienna, and just recently Prof Dr Paetzold of Erlangen delivered at its first session an address on "The Physical Bases of Short Wave Therapy". Paetzold explained that short waves effect a warming of the electrolytes, that is, the solutions of crystal salts, which are present in the body in large quantities and in various forms. Paetzold found that, with a definite resistance and a definite constant in an organism, the maximal heating of the organism (of the electrolyte) is brought about only by a certain wavelength. In general, this maximum is brought about in body fluids by waves from 3 to 15 meters in length. These waves are called ultrashort waves. They have an advantage over the short and long waves in that they produce geometrically straight rays, which can be precisely controlled and given any desired direction. They can easily penetrate otherwise poor conductors so that overheating or burning of the skin is impossible. The easy penetration of the waves makes possible also a particular effect on the deeper tissues. In the transmission of electric heat energy the skin, fatty tissues and bones receive less heat than the parts and organs of the body containing large amounts of fluids. Also the problem of selective heating was hereby solved and the temperature differences between the various layers can be exactly determined. The advantages of the ultrashort waves permit their use especially in rapidly developing inflammatory processes, which is just the opposite of the use of diathermy.

Opposition to Closing the Second Frauenklinik

The ministry of finance has repeatedly urged the ministry of public instruction which controls the affairs of the university to leave in operation only one surgical clinic, one clinic of internal medicine and one gynecologic clinic and to close the others. During recent years one clinic for each of these branches of medicine has been closed so that now there are only two clinics for each of these branches instead of three.

is formerly. Now it has been announced that it is the intention to close also the second Frauenklinik and to leave only the lecture room open. Need of retrenchment is not assigned as the reason for the proposed action, but attention is called to the fact that not only is the ambulatorium less frequented but also the number of births in Vienna has been greatly reduced. Vienna has the second lowest birth rate in Europe. 83 per thousand of population. Only Oslo, Norway, has a lower birth rate. 82. Last year the number of beds in this clinic was reduced from 300 to 68, and patients who could not be admitted, for lack of beds, were referred to the other clinic that was still functioning. But they did not go there but to the hospitals in the provinces. The plan to close the clinic has aroused great indignation. It is emphasized that the decrease in births is doubtless correct but that, on the other hand, the number of miscarriages and cases of disease in women is considerably higher. It is also impracticable to accommodate the large number of students in a single clinic. Moreover, the amount of money saved would be small and is not worth considering as compared with the physical and moral damage that would result for Austrian and foreign students through a reduction in the facilities for acquiring a medical education. The opposition to a purely bureaucratic conception of the problem, which neglects the ethical and politico economic aspects is so general that the hope is justified that the ministries will see the wisdom of reversing their decision.

NETHERLANDS

(From Our Regular Correspondent)

Feb 6, 1934

The Examination of Athletes

Dr J Van Mervenne describes in the *Tijdschrift voor sociale Geneeskunde* the Leeuwarden center for the examination of athletes. The center has four men physicians and one woman physician. Men and women are examined alternate weeks. Of 351 men examined thirty-six were found unfit, eighteen having a circulatory, five a pulmonary, and nine a nervous disorder. Of 193 women examined, ten were found unfit, one having an exophthalmic goiter, two a nervous disorder, six a cardiac disorder and one arthritis.

Infection of Pupils by Their Teachers

The *Handelsblad* of Oct 5 1933, announced that the commune of Oostdongeradeel had voted an appropriation of 500 florins (\$325) to send sixteen tuberculous children to the Sommevank Sanatorium. On making careful inquiries, this journal learned that a teacher in one of the schools of the commune had infected thirty pupils, the sixteen mentioned and fourteen others, who are receiving domiciliary treatment. The same thing happened in one of the De Hoorn schools, where fourteen children became infected and likewise the director of the school. Such catastrophes occur because in many places no medical certificate is required of teachers at the time of their appointment, and during their tenure of office they are subjected to no periodic health examinations.

The Supervision of Diabetic Patients

A committee of physicians met at Utrecht, under the chairmanship of Dr A Hijmans Van Den Bergh, to plan the formation of a national organization for the prolonged treatment of diabetes, in view of the increase in the number of diabetic patients in hospitals, relapses as soon as patients return home and the high percentage of deaths from diabetes. The purpose of the organization is chiefly to establish, with the aid of attending physicians, a regular supervision of diabetic patients in their homes to educate patients and those who care for them to understand the importance of the regimen. A committee was appointed to study the means of effecting the organization proposed.

Disinfection of Swimming Pools

In the hygienic laboratory in Utrecht, Idzerda and Wilder-vanck studied the disinfection of swimming pools. They publish in the *Nederlandsch Tijdschrift voor Geneeskunde* their results. They conclude that the addition of chlorine is preferable in the so called continuous system, provided (a) the time necessary to pass the contents of the pool through the filters does not exceed eight hours, (b) the number of users does not exceed the accepted limits for the establishment in question, and (c) the water lends itself to this method of disinfection. The chloramine method of disinfection should be used for the "periodic" system. The chlorine-copper method of disinfection is in theory an interesting process. The study of the conditions that effect an accelerated disinfection, compared with the action of chlorine alone has not been completed. Hence the application of this method of disinfection is admissible only in case the disinfective action of the water is regularly controlled.

A Blood Transfusion Service

The first blood transfusion service in the Netherlands was organized at Rotterdam by Dr Van Dijk. When the donors are selected they are given a complete examination and, if found fit, receive a card indicating the blood group. The cards are placed on file at a central bureau, where a physician desiring a donor may apply. The donor is reimbursed for his outlays and his loss of time from work.

BUDAPEST

(From Our Regular Correspondent)

Feb 3 1934

The Opening of the People's Hygienic Institute

A five story building has been erected at 3 Eotvos Street, in the heart of Budapest, for the People's Hygiene Museum which was opened recently under the management of Dr George Gortyay, lecturer to the university and ministerial counselor. The organization of this institute is as follows: 1 Directorate 2 Scientific section (a) research collection of material, (b) publications, courses, (c) social activities and the editing of the *Socialpolitika Szataszemle* (Social-Political Press Review) 3 Propaganda section (a) organization of health propaganda, (b) popular lectures, recitals and exhibits 4 Technical section the preparation of exhibits and propaganda material 5 Museum, with eleven sections comprising a vast amount of material 6 Library of 30,000 volumes. Particularly complete is the material relating to industrial hygiene and the alcohol campaign. There is a special reading room in connection with the library, and a public reading room. The institute has forty-five interesting films for use in connection with popular health lectures. Physicians and health institutes may borrow them free of charge.

The Work of the National Public Health Institute

The Hungarian Royal National Public Health Institute, which was opened five years ago, endeavors to apply achievements of modern hygienic studies into everyday life, as well as to train public health workers. Medical officers' courses of nine months' duration have been introduced. In connection with the institute is the "House of Physicians," which provides inexpensive board for graduate students. The institute has also a nurses' training school. The necessity for the training of nurses is shown by the fact that 56 per cent of the nursing staff in the hospitals has had no special training.

To make the campaign against infectious disease more effective, seven provincial bacteriologic testing stations have been erected. While the old central testing station had an average of 3,000 tests annually, the new institute performed 142,272 tests in 1932 and its branches performed 42,327 tests.

The institute introduced the Ramon preventive inoculations against diphtheria in 1929. To the end of 1932, 280,000 children had been given preventive inoculation.

After the thorough examination of 12,000 wells they marked in the villages all those wells which contain pure drinking water with a green cross and with the inscription Good drinking water. The institute tests all Green Cross wells twice yearly.

The institute has supervision also over drugs and proprietary medicines. The necessity for this was indicated by the fact that 92 per cent of all proprietary medicines tendered for registration were found inadequate.

The great effort to improve health conditions in the villages gave birth to the organization of so called model districts of which there are already six. The leaders of these model districts are the district physicians while in the villages the health activities are carried on by the parish doctor, who is assisted in this work by women trained in health work. The institute maintains contact with these women by means of a semimonthly publication entitled the *Green Cross* which informs them of all new phases of public health affairs.

The institute organized the systematic examination of village school children, and introduced the so called lying in huts where sick children are taken from their dark village houses and isolated. For the nutrition of the sick child a goat is kept beside the house.

The leader and founder of this institution is Prof. Dr. Johann, whose work is known beyond Hungary, as shown by the fact that the Council of the League of Nations February 17 appointed him a member of its Public Hygiene Committee which consists of ten delegated members and fourteen elected members.

Insulin Treatment of Schizophrenia

Dr Julius Schuster, late assistant at the university psychoneurologic clinic, made the striking observation that a series of mental patients were under-sensitive to insulin and from this fact he concluded that treatment with insulin might improve their condition. He had asserted previously in the *Archiv für Psychiatrie* (85, No 5, 1928) that insulin has both a direct and an indirect action on the central nervous system. The experiments of Stief in insulin poisoning have shown that insulin is an ectodermotropic drug, and as such therefore acts on the brain cells. Schuster advocated the use of insulin in schizophrenia, with highly satisfactory results. He reported in 1928 more than sixty cases of schizophrenia so treated and since then the number of cases treated has been doubled.

Marriages

HOWARD W. ROGERS, Rome, Ga., to DR. ELIZABETH LYDIA COUNCILMAN of Newburyport, Mass., at Cambridge, February 10.

JOHN MILTON ADAMS, New Haven, Conn., to Miss Carolyn Frances Gaston of Washington, D. C., at New York, March 24.

JOHN LEE MONTGOMERY, Erwin, Tenn., to Miss Maimie Agnes Tucker of Johnson City, February 11.

WILLIAM LE ROY FLEMING, Enfield, N. C., to Miss Edith Mickey Duke of Rocky Mount, March 22.

BARTON McCOSH COOKINGHAM, Rhinebeck, N. Y., to Mrs. Gertrude Havens of Red Hook, recently.

ROY LEE CASHWELL, Fountain Inn, S. C., to Miss Mary Sullivan West of Greenville, March 3.

FELIX WALTER SOKOLOWSKI to Miss Georgia Hale, both of Alton, Ill., at Carlinville, January 14.

GLYNN FITZGERALD BUSHART, Fulton, Ky., to Miss Leonora Amberg of Hickman Ky., March 10.

HENRY HARRISON GIBSON, Akron, Ohio, to Miss Anne Richardson of Sharon, Pa., recently.

VALENTINO B. DI LORETO to Mrs. Frances D. Alessio, both of Steubenville, Ohio, March 15.

Deaths

Jay Frank Schamberg @ professor of dermatology and syphilology, University of Pennsylvania Graduate School of Medicine, Philadelphia, and director of the Research Institute of Cutaneous Medicine, died March 30, of heart disease. Dr Schamberg was born in Philadelphia Nov 6 1870. He graduated from the University of Pennsylvania School of Medicine in 1892, served his internship at the Hospital of the University of Pennsylvania and studied in Vienna, Paris, Berlin, Hamburg and London. He was formerly lecturer on infectious eruptive diseases at his alma mater and professor of dermatology and syphilology at Temple University School of Medicine and Jefferson Medical College. He was a member of the American Dermatological Association and, in 1920 to 1921, president, he was also a past president of the Philadelphia County Medical Society. In 1904 he was a member of the House of Delegates, and from 1928 to 1929 chairman of the Section on Dermatology and Syphilology, American Medical Association. In collaboration with Drs Raiziss and Kolmer, Dr Schamberg was responsible for the synthesizing of arsphenamine in this country during the World War. He was the author of "Skin Diseases and Eruptive Fevers," and "Compendium of Diseases of the Skin" and co-author of "Acute Infectious Diseases and "Treatment of Syphilis". Dr Schamberg was elected to the editorial board of the *Archives of Dermatology* in 1927 to fill the unexpired term of Dr Hartzell, who died. In February 1928 he was reelected and served until February 1934.

JAY FRANK SCHAMBERG, M.D.
1870-1934

Charles Henderson Miller @ Chicago, Northwestern University Medical School, Chicago, 1898 formerly a pharmacist, at one time assistant professor of pharmacology at his alma mater and professor of pharmacology and therapeutics Bennett Medical College, aged 66 one of the founders and on the staff of the Woodlawn Hospital, where he died March 12 of embolism hypertension and coronary thrombosis.

Joseph G Perrault, St Albans Vt School of Medicine and Surgery of Montreal, Que Canada 1898, member of the Vermont State Medical Society past president of the Franklin County Medical Society for twenty-five years justice of the peace, at one time member of the city council and health officer, on the staff of St Albans Hospital aged 61 died January 31, of pneumonia.

Charles Galen Weston, Winter Park Fla Harvard University Medical School, Boston 1882, fellow of the American College of Surgeons past president of the Hennepin County (Minn) Medical Society formerly on the staff of the Hill Crest Surgical Hospital Minneapolis aged 75 died March 2 in the Victoria Hospital, Miami of acute hemorrhagic nephritis and bronchopneumonia.

Josiah Wellington Crane, Trenton N J, University of the South Medical Department Seavane Tenn 1900 member of the Medical Society of New Jersey and the American Academy of Ophthalmology and Oto-Laryngology medical director of the New Jersey State Prison Hospital aged 56 died February 18, at Rochester Minn of gastro intestinal fistula and bronchopneumonia.

Charles Clark Ammerman @ Surg Lieut Commander U S Navy, retired Elmira N Y George Washington University Medical School Washington D C 1906 entered the

navy in 1921 and retired in 1932 for incapacity resulting from an incident of service aged 63, died, March 20, in the United States Naval Hospital San Diego, of chronic nephritis.

John Baker Swift, Jr @ Boston, Harvard University Medical School, Boston, 1908, member of the New England Obstetrical and Gynecological Society and the New England Pediatric Society, instructor in obstetrics at his alma mater, on the staff of the Massachusetts General Hospital, aged 50, died suddenly, March 9, of heart disease.

Samuel Erskin Mitchell @ Muskogee, Okla, University of Nashville (Tenn) Medical Department, 1900 past president of the Haskell County Medical Society and the Muskogee County Medical Society, served during the World War, on the staff of the Veterans' Administration Facility aged 61, died, February 23.

Keeton Alexander, Lockhart, Texas, Louisville (Ky) and Hospital Medical College, 1908, member of the State Medical Association of Texas, past president of the Caldwell County Medical Society, past president of the school board of McMahan, aged 52 died March 8, of uremia.

Rollo Orly Payne, Ontario Ore Marion-Sims College of Medicine, St Louis 1899, Medico Chirurgical College of Philadelphia, 1903, member of the Associated Anesthetists of the United States and Canada, for many years county coroner, aged 56, died, Dec 25 1933.

William Francis Flanagan, Apponaug R I, Long Island College Hospital, Brooklyn, 1900 fellow of the American College of Surgeons, visiting surgeon to St Joseph's Hospital, Providence, aged 61, died, February 20, of carcinoma of the tongue and cervical glands.

Henry Green @ Dothan, Ala, Medical College of Alabama Mobile, 1892 past president of the Medical Association of the State of Alabama and the Houston County Medical Society, on the staff of the Moody Hospital, aged 67, died, February 22, of cerebral hemorrhage.

Robert Mortimer Jones, New York New York Homeopathic Medical College and Hospital, 1896, served during the World War, aged 63, died, February 21, in the New York Homeopathic Medical College and Flower Hospital, of hemorrhage due to gastric ulcer.

Galen Edwin Moyer @ Elvira, Ohio University of Pittsburgh School of Medicine, 1917, served during the World War, on the staff of the Elvira Memorial Hospital, aged 46, died February 3, in the Cleveland Clinic Hospital, of diabetes mellitus.

Edward Payson Crowell, Brooklyn, Long Island College Hospital, Brooklyn 1883, member of the Medical Society of the State of New York for many years member of the board of education, aged 77 died, February 27, of heart disease.

John Francis Dwyer, Corning, N Y Ohio Medical University, Columbus 1905, member of the Medical Society of the State of New York, on the staff of the Corning Hospital, aged 53 died, February 21 of heart disease.

Anna Sophia Windrow Holm, Chicago College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1901, aged 73, died March 15 of arteriosclerosis and myocarditis.

Harry Wilson Porter, Louisa, Va, University of Virginia Department of Medicine, Charlottesville, 1896, member of the Medical Society of Virginia aged 59, died, February 20 of cerebral hemorrhage.

George H Harper, Monroeville, Ala Atlanta College of Physicians and Surgeons, 1902 member of the Medical Association of the State of Alabama aged 59, died February 16, of emphysema.

Carmotte Ashley Cobb Beaumont, Texas, Tulane University of Louisiana Medical Department New Orleans 1902 served during the World War aged 57 died February 25, of myocarditis.

Alexander L Mathews, Callaway Neb Eclectic Medical Institute Cincinnati 1882 member of the Nebraska State Medical Association aged 84, died February 12, of hypostatic pneumonia.

John Milton Messinger, Oakfield, N Y University of Buffalo School of Medicine 1923, aged 34 died February 25 in the Glockner Hospital Colorado Springs following an operation.

Charles Andrew Haas St Paul University of Minnesota College of Medicine and Surgery Minneapolis 1894 aged 59, died January 22 in St John's Hospital, of carcinoma of the stomach.

Ernest Chandos Blackwell, Los Angeles, Bellevue Hospital Medical College, New York, 1895, aged 62, died, January 20, of chronic osteomyelitis of the left femur and myocarditis

John Benjamin Wrightsman, Denver, National Normal University College of Medicine, Lebanon, Ohio, 1890, aged 77, died, February 21, of chronic myocarditis and nephritis

Lester Orlo Houghten, Ironwood, Mich., University of Michigan Medical School, Ann Arbor, 1906, fellow of the American College of Surgeons, aged 52, died, March 15

George Norfleet Harrell, Grimesland, N C., University College of Medicine, Richmond, Va., 1907, aged 52, was found dead in his office, February 16, of cerebral hemorrhage

John H Hammond, Georgetown, Del., Medico-Surgical College of Philadelphia, 1889, aged 65, was found dead, February 22, with a bullet wound in the head

Cassius Harriot Darling, Worcester, Mass., University of the City of New York Medical Department, 1883, aged 74, died February 28, of cerebral hemorrhage

William R Hamilton, Weiser, Idaho, Victoria University Medical Department Coburg, Ont., 1892, formerly mayor, aged 67, died, February 13, of erysipelas

Clayton S Woolston, Spencerport, N Y., University of Buffalo School of Medicine, 1897, aged 60, died, February 5, in St Petersburg, Fla., of angina pectoris

William Frazier Tift, Long Beach, Calif., University of Vermont College of Medicine, Burlington 1880, aged 78, died January 14, of carcinoma of the prostate

Fischer Randall Jordan, Oakland, Calif., Cooper Medical College, San Francisco, 1895, aged 60, died, January 26, of chronic prostatic staphylococcus infection

John Spencer Gallagher, Salem, Ohio, Western Reserve University Medical Department Cleveland, 1887, aged 72, died suddenly, February 21, of heart disease

J F J Hood, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1901, aged 65, died February 19, in the Grady Hospital, of pulmonary tuberculosis

John Arrington, Blewins, Ark., licensed in Arkansas, year unknown, aged 57, died, February 2, in the Donnell Hospital, Prescott, of cerebral hemorrhage

Sharon C Newell, Helena, Mont., Columbus (Ohio) Medical College 1880, aged 77, died, January 2, in St Peter's Hospital, of chronic myocarditis

David Hunter McAlpin & Morris Plums, N Y., Bellevue Hospital Medical College, New York, 1888, aged 72, died, January 20, of arteriosclerosis

James Winfield Sampsel, Penns Creek, Pa., Jefferson Medical College of Philadelphia, 1878, aged 82, died, February 28, of cerebral hemorrhage

Andrew Harrison Weber, Chicago, Drake University Medical Department, 1895, aged 67, died, February 17, of organic heart disease

W A Hawkins, Dallas, Texas, (licensed in Texas, under the Act of 1907), aged 50, died, Nov. 15, 1933, of gas poisoning, self-administered

Thomas Hugh G Cook, Weslaco, Texas, Medical College of Alabama, Mobile, 1886, aged 68, died, February 18, of chronic endocarditis

George Zinn, Klemme, Iowa, Physio-Medical College of Indiana, Indianapolis, 1897, aged 66, died suddenly, January 29, of heart disease

Uriah Edward Bateson, London, Ont., Canada, Trinity Medical College, Toronto, 1889, aged 67, died, January 30, of heart disease

Anderson P Barclay, Wharton, Texas, Memphis (Tenn.) Hospital Medical College, 1901, aged 67, died, January 10, of heart disease

Warren Burd West, St Anthony, Idaho, Missouri Medical College, St Louis, 1897, aged 64, died, Dec. 18, 1933, of heart disease

Claude Reznor Leech & Walnut Creek, Calif., Cooper Medical College, San Francisco, 1894, aged 65, died, January 13

William Bell Wood, South Pasadena, Calif., Missouri Medical College, St Louis, 1875, aged 82, died, February 25

M D Empson, Galatia, Ill., Missouri Medical College, St Louis, 1882, aged 77, died, March 6, of hypostatic pneumonia

Wilmot Leland Ransom, Rockford, Ill., Chicago Medical College, 1874, aged 81, died, March 12, of lobar pneumonia

Correspondence

POSTERIOR PITUITARY IN PYELITIS

To the Editor—The interesting article of Ward Darley and W B Draper in *THE JOURNAL* (March 3, p 677), emphasizing atony of the musculature of the renal pelvis and ureter with the resultant sluggish drainage as an important factor in the development and course of pyelitis, refers to the experimental work of Gruber. He showed that the ureteral muscle responds with increased peristalsis to solution of pituitary (*J Urol* 20 27 [July] 1928), as they confirmed (*J Urol* 26 1 [July] 1931).

At the meeting of the American Gynecological Society in 1927 I presented a preliminary report of work done at Johns Hopkins on the etiology of pyelitis gravidarum, in which the occurrence of dilatation and atony of the upper urinary tract as physiologic phenomena in pregnant woman was stressed. The use of solution of pituitary was suggested for stimulating ureteral peristalsis in cases of pyelitis gravidarum that do not yield to the routine treatment of forcing fluids and administering alkalis. Reports of the work were published in the *Bulletin of the Johns Hopkins Hospital* (42 118 [March] 1928) and in the *Journal of Urology* (20 413 [Oct] 1928). The article by Gruber quotes my experimental data. The use of postpituitary was advocated by me also during the puerperium in cases of pyelitis as an attempt to forestall the persistence of ureteral dilatation which, in my series, was observable in about 40 per cent of cases of pyelitis for months or years after the termination of labor. Recently I substituted ampoules of pitressin for the original solution of pituitary in order to eliminate the osmotic factor. For the last few years, I have been using ampoules of pitressin in addition to ureteral catheterization in selected cases of pyelitis in order to obtain prompt relief.

J I HOFDAUER, M D, Cincinnati

STANDARDIZATION OF DIGITALIS

To the Editor—I was much interested in the communication published in *THE JOURNAL*, March 17, and purporting to come from the Heart Committee of the New York Tuberculosis and Health Association, although it is signed by the "Digitalis Committee." Whether these two committees are in reality two or whether they are one and the same under different names I am unable to say. Before discussing the contents of the communication I would point out that it should more properly have been addressed to Professor Cook, the chairman of the U S Pharmacopoeial Revision Committee, which has the matter of biologic standardization of digitalis and other drugs in charge, and it would doubtless have been referred to the proper subcommittee, where I am sure it would have received careful and sympathetic consideration. However, I am tempted to consider some of the points raised by it, as they have been for some time a source of considerable anxiety to many of us who are interested in and are working for simplicity and accuracy in the act of prescribing.

The committee is correct in stating that a frog method is official in the U S Pharmacopoeia. The reason for this lies in the fact that three subcommittees of the U S Pharmacopoeia viz., the committees of the 1910 revision, the 1920 and now the 1930 revision have voted unanimously to include a frog method of assay in preference to a cat method. These three committees were in each case composed of medical men, pharmacologists and pharmacists who had special interest in and knowledge of the biologic standardization problem. The decision in the case of each of the three revisions has been made by the different committees after one or more meetings with representatives of the large pharmaceutical houses engaged in biologic standardization of their products. In not one instance, as my

memory serves me, and I have been chairman of these subcommittees since the 1910 revision, has a single manufacturing pharmacist advocated the adoption of a cat method of assay. As a matter of fact, at each of these combined meetings pharmacist after pharmacist has said that it would be practically impossible for his firm to carry out such assays on cats, as they could not get enough animals to meet all their needs. It is one thing to assay a powder for one limited group of specialists and quite a different problem to assay the products of a large manufacturing house supplying perhaps a nation-wide demand for its digitals, to say nothing of the trade beyond the seas. If the pharmacists are so dissatisfied with a frog method of assay and are anxious for a cat method, why have their representatives for twenty-five years voted unanimously against the adoption of a cat method? At our conferences not one manufacturer has urged its adoption.

The statement that the majority of pharmacologists favor the cat method is equally open to serious question, not to make a stronger statement. Where did the "Committee" secure this information? To the best of my knowledge such a question has never been put up to the Pharmacological Society or to any authorized group of pharmacologists. I imagine the nearest approach to such a group consideration of the question would be the pharmacopeial subcommittee on biologic standardization which includes several pharmacologists and it has voted unanimously against the cat method. But even in this group there are relatively few pharmacologists. In other words, no one knows—the "Committee" I or any one else—what the majority of pharmacologists do favor, for to the best of my knowledge they have never expressed an opinion nor even have been asked to do so. Certain individual pharmacologists have expressed opinions pro or con but I would say comparatively few—certainly not so that any one can say what the "majority" of pharmacologists favor.

However, there is another aspect of the matter which is of grave importance as tending to therapeutic confusion. This is the use of the term "cat unit." Why should such terms be in use at all? What is gained except confusion? The only object in carrying out an assay be it chemical or biologic, be it by frog or by cat is to secure to the physician and patient a uniform potent preparation. It cannot in any way be used as an index to the amount of a drug to be given a patient. There is therefore no occasion or logical reason for the use of the term "cat unit." Other drugs are given in grams or grains, cubic centimeters or minims. Why then coin a new system of weights and measures for digitals? But the evil has gone even beyond this. There are now not only cat units but "international cat units" and one is led to wonder how many practicing physicians to say nothing of cardiologists, know the difference between the two. As if these were not enough, there are "frog units" of digitals, "heart tonic units" and "guinea pig units" and all equally illogical as the cat unit, national or international. Could confusion be worse confounded? There might with equal logic be cock units of ergot, dog units of cannabis, dog units of epinephrine solution and so on ad nauseam. There is nothing scientific about such a system. What general practitioners and cardiologists want I repeat is a uniformly potent preparation of digitals. Neither cares really how this is obtained whether on a cat, dog or frog. And he can get this uniform preparation by prescribing a pharmacopeial tincture made by some one of the firms in whose products he has confidence. They should know that in prescribing such a pharmacopeial tincture they will get one that is constantly under government supervision and control.

Finally, in what I have written I hope I have made the position of the Pharmacopeial subcommittee clear. It is grateful for criticisms and suggestions. It is unfortunate that not one of the signers of the Committee's communication found it

convenient to attend the Pharmacopeial convention in 1930 when the Revision Committee was selected. Without any doubt any one of them could have been elected a delegate to the convention if he had expressed the slightest desire and he would then have been eligible for election to the Revision Committee and if so elected could have served on the Subcommittee on Biological Standardization, where his knowledge and experience would have been of tremendous help in solving a very difficult problem.

C. W. EDMUNDS, M.D., Ann Arbor, Mich.
Chairman of the Subcommittee on Biological
Standardization of the U. S. Pharmacopeial
Revision Committee

To the Editor—The digitalis committee (THE JOURNAL, March 17, p. 862) endorses the cat method for the standardization of digitalis and gives some valuable information concerning it. It then states that tablets of digitalis leaves made up to the strength of 1 cat unit, $\frac{1}{2}$ cat unit and 2 cat units have proved satisfactory in clinical use. Also liquid preparations of digitalis should be put up so that 1 cc. contains the equivalent of 1 cat unit.

I should like to ask. In clinical work why not leave the cat in the laboratory? What clinicians want is an assured active preparation. Most of them do not know what a cat unit means and why should they be asked to remember it? It adds only to confusion to say that 1 cc. contains a cat unit. If the cat must be mentioned it would be sufficient to state that the preparation was standardized by the cat method.

H. A. MCGUIGAN, M.D., Chicago

[The letter of Dr. McGuigan was referred to Dr. Levy, who replies.]

To the Editor—The suggestion of Dr. McGuigan that the cat be "left in the laboratory" is, unfortunately, not feasible. The dosage of any form of medication must be gaged by its potency. When the chemical composition of a drug is known, the dose can be expressed in terms of weight or volume. But equivalent weights or volumes of digitalis preparations are not necessarily equal in potency. In the case of biologically standardized products there must be some unit of strength by which the effects on man may be estimated. The term "unit" is one with which the practitioner is already familiar and which he employs daily in prescribing insulin, diphtheria antitoxin and the vitamin products. A unit there must be, and since, in the assay of digitals, various methods are still in use, accuracy of definition makes it necessary to refer to the "cat unit."

ROBERT L. LEVY, M.D., New York
Chairman Digitalis Committee

HODGKIN'S DISEASE IN BROTHERS

To the Editor—In THE JOURNAL, February 17, McHaffey and Peterson reported two cases of Hodgkin's disease occurring simultaneously in brothers. Reference was made to the rarity in which this condition occurs in more than one member of a family. I wish to report another instance of two cases occurring in brothers.

A C. a man aged 32 came to the surgical dispensary at Northwestern University Medical School April 13, 1931 complaining of a swelling in the right axilla of one year's duration. Examination at that time revealed several indurated discrete axillary nodes. There was moderate enlargement of the spleen. The blood count indicated 6,125 white blood cells with a normal differential count save for 3 per cent eosinophils and 4,760,000 red blood cells with 85 per cent hemoglobin. The patient stated that a biopsy had been made three months previously at Epworth Hospital, South Bend, Ind. A laboratory report subsequently

obtained from the Epworth Hospital furnished pathologic evidence of the diagnosis Hodgkin's disease. The patient was given three courses of roentgen treatments with temporary benefit but died in March 1934. At that time there was involvement of the cervical nodes along the posterior border of the right sternomastoid muscle and roentgenographic evidence of enlargement of the mediastinal nodes.

When first examined, the patient stated his brother, H. C., had died of Hodgkin's disease seven years previously at the age of 27. Diagnosis was made at the University of Michigan hospital. A report obtained from the University of Michigan is as follows: "On examination it was found that there was an enlargement of the lymph glands more marked on the left side of the body, especially in the cervical region. The liver was found to be slightly enlarged and the spleen was large and firm. Laboratory examinations showed a marked increase of mononuclears and transitionals. The final diagnosis was Hodgkin's disease." He later was given roentgen treatment but died three years after the first glandular enlargement was discovered. The diagnosis was confirmed by subsequent biopsy at the Epworth hospital in South Bend.

W. KENNETH JENNINGS, M.D., Winnetka, Ill.

USE OF OTOSCOPE FOR UMBILICAL EXAMINATION IN OBESITY

To the Editor—I wish to make a simple suggestion which I have found of considerable value to me on two occasions in the past few weeks in rather difficult examinations. Recently two obese women whom I saw complained of intermittent, purulent, excoriated discharges from the umbilicus. Each had had previous surgery done. Because of the obesity the umbilicus could not be everted in the usual manner, and so I used an ordinary electric otoscope with a rather large speculum which gave a perfect view of the floor and side wall of the umbilical cavity, and in one patient showed a tiny sinus in the floor, discharging pus.

In view of the marked difficulty that I have previously experienced in examining this type of patient, I thought this suggestion worth passing along.

H. V. FINDLAY, M.D., Santa Barbara, Calif.

BRONCHIAL ASTHMA IN PREGNANCY

To the Editor—After reading the paper entitled "Bronchial Asthma as a Complication of Pregnancy," by Dr. Bradford Green (*THE JOURNAL*, February 3, p. 360), I feel that a comment made from a different angle is proper. The obstetrician is naturally struck by the aggravation of asthma during pregnancy, for it offers a disturbing complication to him. This may lead him to a broad conclusion, as "in a patient with true bronchial asthma of anaphylactic origin, the attacks are markedly exacerbated by pregnancy." However, to the internist interested in allergy, cases of equal interest are those in which allergic manifestations disappear during pregnancy.

That this occurs was first demonstrated to me nine years ago while supervising the allergy work in the department of internal medicine at the University of Michigan. The first patient with such a story was a highly educated, intelligent woman who had been through four or five pregnancies, with freedom from both asthma and hay fever during such times. The recollection of this case is vivid because she reiterated that she welcomed pregnancy because of freedom from allergic symptoms. Since then I have had a number of cases in which there was relief from asthma, hay fever and allergic migraine during pregnancy. In order to meet the argument that these manifestations may have been associated with the menstrual

period and so relieved during pregnancy, it should be stated that the patients have been proved sensitive to foods or pollen, with no relation to menstruation. This is proved to a nicety by the fact that a seasonal manifestation of allergy, such as hay fever, recurring yearly, may be absent entirely if pregnancy includes the months of hay fever incidence. I shall not go into speculations on the interesting fact that pregnancy may have a favorable effect on allergic responses.

I feel that the practitioner should realize that, though in some patients pregnancy may aggravate allergic manifestations, in others it may have the opposite effect.

R. H. KAMPMEIER, M.D., New Orleans.
Assistant Professor of Medicine, Louisiana
State University Medical Center

Queries and Minor Notes

A ANSWERS COMMITTEE considers queries on postal cards will not be noticed. Every letter must contain the writer's name and address but the name will be omitted on request.

MENSTRUATION, OVULATION AND THE SAFE PERIOD

To the Editor—I am unable to understand just what you regard as the safe period in the menstrual cycle. On page 861 of the March 17 issue of *THE JOURNAL* Dr. Emil Novak says there is no difference between the Knaus plan of counting forward ten to seventeen days from the first day of the preceding period to derive the safe span and the Ogino method of counting back twelve to nineteen days. On page 864 of the same issue under "Sterility and Artificial Insemination" you say the most favorable time to carry out this procedure is the ten days that occur midway between the menstrual periods. On page 864 under "Diagnosis and Treatment of Aspermia" you say that the best time to inject the spermatozoa is shortly after the cessation of menstruation. Of course all this is confusing as to when you mean the safe span is. But to complicate it Dr. G. L. Moench on page 866 states that the spermatozoa live for two weeks or so in the uterus and tubes. So how can you consider any time as being safe with that possibility?

EDWARD P. LEEPER, M.D., Dallas, Tex.

Answer—An examination of the various sources of information quoted by the correspondent reveals no conflict of views to justify the quandary under which he is apparently laboring. In the letter of Dr. Emil Novak, on page 861, the ovulation period (i.e., the period that is not "safe") is given as embracing the span between the tenth and seventeenth days of the twenty-eight day cycle, although, in his original paper in *THE JOURNAL* (February 10, p. 452) Novak believes it safer to consider the "dangerous" period as extending from the eighth to the twentieth days.

In the answer to the query on page 864 the round statement is made that the most favorable time for artificial insemination is the ten days midway between the periods, and this is explained, in the next sentence but one, by the statement that "ovulation may occur at any time from the tenth to the eighteenth days of the cycle" virtually the same period emphasized by Novak.

In answer to the query on aspermia (p. 864) the statement is made that artificial insemination should be done "shortly after the cessation of menstruation," and this is not very explicit. From what has been said as to the usual time of ovulation, this procedure would be more likely to be successful if carried out after the eighth or tenth day of the cycle. It is possible that ovulation might occasionally occur just after menstruation, but this is certainly not the rule.

Finally, the correspondent has obviously read incorrectly Dr. G. L. Moench's note (p. 866) as to how long the spermatozoon retains its potency after its entrance into the female genital canal. He explicitly states that "the limit is certainly not more than thirty-six to forty-eight hours," about the same as quoted by Novak from Ogino and Knaus. The little with which chastity has apparently been lost upon the correspondent is again submitted to him for careful study and analysis with one grammatical improvement which may make it clearer: "The presence of living sperms in the female genital canal allegedly two weeks after intercourse is no longer a scientific question but a moral issue."

With one exception all the authors quoted by the subscriber, therefore, are in essential accord as to the time at which ovula-

tion occurs, and as to the duration of potency in the male sperm. These two factors, together with the now generally accepted view that the life of the extruded ovum is short, constitute the basis for the concept of a "safe period," and this is apparently supported by considerable clinical evidence. However, as Novik has emphasized, it would be premature to consider the question closed or to regard this method of birth control as infallible, as some authors seem inclined to do.

SYPHILIS AND PREGNANCY

To the Editor—A white woman aged 26, married three years inquires as to the advisability of becoming pregnant. She is in good health has never had any symptoms of syphilis, and has always had a negative Wassermann reaction. Her husband aged 30 contracted syphilis presumably about eight years ago. It was undiagnosed until two and one half years ago when he was found to have a 4+ blood Wassermann reaction. Treatment by means of two courses of neosarsphenamine and sodium bismuth thioglycollate was administered. The blood Wassermann reaction remained positive and a test of the spinal fluid was found to be 4+. The colloidal gold curve was tabetic. Two courses of tryparsamide and iodobismutol were given. The blood and spinal fluid are now negative in all respects. The patient has had lightning pains of moderate severity for about two years. These have become less frequent since the last two courses of treatment. There have been two attacks of abdominal pain believed to be tabetic crises. The reflexes and all eye phenomena are normal. The general condition is good and there are no other symptoms. Is there any danger of the wife's contracting the disease if she becomes pregnant that is could it be transmitted to her in the semen? What are the chances of syphilis in the child? I should also appreciate any suggestions you could give for the further medical management of the husband. Please omit name and address.

M D Illinois

ANSWER—In view of the frequency of conjugal and hereditary neurosyphilis it would seem inadvisable for this patient to become pregnant. The question of whether or not there is a special strain of spirochetes that has a predilection for the nervous system is still being debated. There is a definite danger of the wife's contracting the disease if she becomes pregnant. Even if the child should not show active syphilis at birth, it might show evidence of a neuropathic heredity in later life. The possibility of such conditions as hydrocephalus, juvenile tabes, idiocy and imbecility should be borne in mind. The prognosis in tabes with a markedly positive Wassermann reaction of the blood and spinal fluid is not good, even though the manifestations have become negative under treatment. Whereas a certain percentage of cases may remain quiescent or may be arrested by active treatment, the majority of cases presenting lightning pains and tabetic crises are progressive and sooner or later ataxia, bladder symptoms or ocular disturbances develop. The medical management of tabetic cases presents many problems. As long as treatment with tryparsamide and iodobismutol has proved beneficial, it should be continued. Between courses, mercurial inunctions and iodides may be administered. The eyes should be frequently checked by a competent ophthalmologist. Hydrotherapy, massage, fever therapy and reeducation methods have a limited use in the management of advanced tabes.

TRICHINOSIS

To the Editor—What is the possibility of the introduction of trichinosis through an open wound? The larvae of the trichina were found in blood smears within two weeks after a large lacerated skin wound had been received. There were no referable gastro intestinal symptoms and the patient was absolutely certain that no form of pork had been eaten. Please omit name.

M D New Jersey

ANSWER—There does not seem to be any evidence that human trichinosis has been introduced into the body through wounds of the skin. The entrance of adult impregnated trichinae through such a wound is, however not inconceivable and it is of interest to note that in susceptible animals the injection of female trichinae with mature embryos may be followed with muscular invasion by the embryos (Berger E. and Stähelin, A. *Centralbl f Bakt* (abt. 1) 107 377 [June 20] 1928, 111 144 [Feb 16] 1929. Doerr R. and Schmidt G. W. *ibid* 113 271 [July 30] 1929). This result has been obtained on injection of female trichinae directly into the muscle as well as into the circulation. Demonstration of trichinous larvae in the blood makes the case in question one of unusual interest. The first and apparently so far the only other demonstration of trichinous larvae in the circulating blood in man is by W W Herrick and Theodore C Janeway (Demonstration of *Trichinella Spiralis* in the Circulating Blood in Man. *Arch Int Med* 3 263 [April] 1909) who found them in fresh samples of blood after taking with 3 per cent acetic acid

DERMATITIS FROM SPUN GLASS CHRISTMAS TREE ORNAMENTS

To the Editor—I recently came in contact with a dermatitis of the hand. The patient attributes the condition to the handling of some Christmas tree ornaments made of spun glass. These Christmas tree ornaments go under the name of 'angels' hair'. They are manufactured by the Strauss Eckhardt Company Inc 35 East Seventeenth Street New York. The dermatitis was of the trichophytosis type. I should be grateful for your opinion as to whether or not there have been other complaints of a similar character. The occurrence of a dermatitis from the handling of this article.

C N RAMSAY M D Cleveland

ANSWER—No record of a similar case, nor any sort of dermatitis from spun glass, has been found. The Strauss Eckhardt Company imports 'angels' hair' from Germany and in response to an inquiry states the belief that it is made of glass alone. The company does not know anything about the process of manufacture but expects further information from the manufacturers. To date this has not been received. It is possible, of course, that mechanical irritation from fine glass might cause a dermatitis if it was handled a great deal, but it is unlikely that it would cause a vesicular dermatitis resembling eczematoid ringworm.

The question of mechanical irritation can be tested by rubbing a small area of skin with the 'angels' hair' and another small area with some neutral substance, such as the back of a steel or silver (not nickel) knife blade. Both methods should cause a patch of dermatitis if the dermatitis is a mechanical one. If there is some irritant other than glass, the area rubbed by the glass would cause a dermatitis, the other not. Then a patch test with a small portion of the 'angels' hair' should be made, covered with a square of oiled silk, oiled paper, rubber dam or gutta percha and fastened with adhesive tape. After two days the result can be read according to the presence or absence of dermatitis on the area touched by the 'angels' hair'. If a positive reaction is obtained, a report of the case should be made.

PROPHYLAXIS OF AMEBIASIS

To the Editor—The recent articles on amebiasis leave one thing to be desired namely prophylaxis. It seems incredible that such an epidemic as that in Chicago could have come from such gross carelessness of personal hygiene as would have occurred on the part of an employee and one wonders whether some garden that furnished the hotel with salad vegetables might not have been fertilized with human excreta. How can lettuce and celery be cleaned to make them safe to be eaten raw? If a person with amebiasis should accidentally contaminate his fingers how would he proceed to disinfect them? Would there be danger to the family from lavatories faucets and towels? Please omit name.

M D California

ANSWER—Soon after cases of amebiasis were recognized in Chicago in 1933, careful inquiries proved that the vegetables bought by the hotel in question came from the same markets as those of other hotels in which cases of amebiasis did not occur. General inquiries regarding the source of all vegetables sold in the markets failed to reveal evidence of fertilization with human excreta.

Lettuce and celery, if thoroughly washed in rapidly flowing, pure water should be safe for eating raw.

Persons with amebiasis should pare the nails close to the fingers. The hands, and especially the fingers, should be thoroughly scrubbed with a nail-brush frequently, and always after using the toilet. The hands should then be dipped either in a weak solution of cresol or in alcohol before drying.

With reasonable care, there should be no danger to the family from lavatory or faucets. But an infected person should have a towel exclusively for his own use and kept free from reach of other members of the family.

EDEMA OF EYELIDS

To the Editor—A male patient with bilateral non nephritic edema of the eyelids upper and lower is desirous of having something done. There is no history of irritation. Please omit name.

M D Massachusetts

ANSWER—First the cause should be found, if that is possible. In some of these cases chronic inflammatory conditions in the accessory nasal sinuses are responsible for the edema. In others the edema may be a local manifestation of generalized trichinosis again there may be a localized dermatitis of the upper and lower lids underlying the edema and in many of the cases, no demonstrable cause can be found. If the usual treatment is unavailing and the disfigurement is considerable, oval or crescentic strips of the skin may be excised from the upper and lower lids provided not too much is removed.

ENDOCRINE OBESITY

To the Editor—A woman aged 26 came to me on account of obesity and amenorrhea. Her childhood history is negative except for chickenpox and measles. The father is heavy set and has diabetes. One sister slightly older than the patient is also considerably overweight and a brother has a tendency toward obesity. The patient is short. Menstruation began at the age of 12 and has always been irregular from a few days to one month when it first began. Later it lasted four or five days with a profuse flow, no clots and no backaches or pain. The last period was more than two years ago previous to her marriage, since which time she has not menstruated. The discharge is yellowish. The patient has no libido but gets ordinary satisfaction from sex relations. She states that formerly when she went a couple of months without menstruating she gained weight, which was lost when she began menstruating. She tires easily, has spells of nausea and cramps and is not short of breath. Constipation alternates with diarrhea. She has not been able to conceive. She is 59 inches (150 cm) in height and weighs 256 pounds (116 kg). She states that before her marriage she weighed 140 pounds (63.5 kg) and has gained 25 pounds (11.3 kg) in the last three months. She is very intelligent. She has a small amount of hair on the upper lip and face which has increased in the last two years. Her teeth are far apart. Obesity seems to be more pronounced on the shoulders and abdomen. The genitals are fairly normal in size. The uterus cannot be felt owing to the extreme obesity. The breasts are larger than usual. Roentgen examination shows a normal sella turcica but the frontal sinuses are underdeveloped. Laboratory examinations show normal blood chemistry and urine. The Wassermann reaction is negative. The basal metabolic rate is plus 3.08 per cent. An electrocardiogram showed a deep Q in the third lead which usually is significant of myocarditis. I have placed the patient on a 1500 calory diet and given her desiccated thyroid and the anterior pituitary like principle from the urine of pregnancy in the hopes of making her menstruate. In seven weeks she has lost 24 pounds (11 kg) but so far has not menstruated. Previous treatments with injections of theelin have also failed to bring menstruation. This is beyond question a pituitary disturbance with no doubt a family predisposition to glandular dysfunction. I have given her thyroid principally because her heart rate was 70 and blood pressure 120 and the fact that the basal metabolic rate is plus 3 for such a person is below normal in view of her surface area. Suggestions toward reducing the patient scientifically and also with respect to bringing about menstruation will be greatly appreciated. Would you advise using dinitrophenol in such a definite glandular case? Please omit name.

M D Missouri

ANSWER—The case is compatible with a hypofunction of the anterior pituitary gland, resulting in a decreased gonadal activity. The treatment seems adequate from the standpoint of weight reduction. However, it would be advisable to continue the use of either of the estrogenic preparations used until, and for some time after, the weight has returned to normal, before passing final judgment on their adequacy. In view of the patient's apparent resistance to the action of these endocrine preparations, it might be better to administer them in short courses, allowing rest periods in between. There is nothing to be gained by the use of dinitrophenol.

TOXICITY OF ETHYLENE DICHLORIDE AND OF TRICHLOROETHYLENE

To the Editor—One of our local firms is using ethylene dichloride in manufacturing its adhesive line consisting of library pastes and glues. There is a chloroform like odor which has several times nauseated an employee or two. I should like to know whether there is any harm that might arise from this.

M D Iowa

To the Editor—I am interested in obtaining some information on the relative toxicity of ethylene dichloride ($C_2H_4Cl_2$) and trichloroethylene (C_2HCl_3) and any health hazards attendant on the use of these solvents for industrial purposes. I note in THE JOURNAL April 16 1932 page 1401 a statement in reply to an inquiry that ethylene dichloride is more toxic than trichloroethylene. I would appreciate receiving any information that the Association may have as to specific tests on the relative toxicity of these two products.

L New York

ANSWER—Ethylene dichloride ($C_2H_4Cl_2$) is a member of a group of chlorinated hydrocarbons and is similar to carbon tetrachloride, trichloroethylene and chloroform. All these substances are toxic. The order of its toxicity may be inferred from the following list of various solvent intoxicants in terms of diminishing toxicity: benzene, ethylene dichloride, trichloroethylene, carbon tetrachloride, gasoline (boiling point 90°C), naphtha and Stoddard's solvent.

Ethylene dichloride has come into fairly extensive use as a solvent and extractive. Toxicity begins at about 500 parts of the vapors of ethylene dichloride per million of air. Manifestations are similar to those from carbon tetrachloride. These usually begin with nausea, headaches, mild respiratory irritation and diarrhea but culminate in gross injury (which may be temporary) to the liver with symptoms of, or simulating, guanidine poisoning.

In 1932 the department of industrial relations of the state of Ohio found itself involved in litigation with reference to its code governing dry cleaning operations. In hearings, extensive data were presented concerning the relative toxicity of carbon

tetrachloride, ethylene dichloride and trichloroethylene. This material has not been published beyond the point of hearing records.

A part of the testimony consisted of the presentation of the results of animal experiments in which the substances mentioned had been tested by respiratory administration and by skin application. In this work rabbits were utilized as experimental subjects. The rabbit is perhaps not as well suited for this type of experimentation as are dogs or monkeys.

Exposure was provided to various concentrations of vapors, and various quantities of the liquid were applied to the skin. Certain animals promptly died, others in the lower concentration series were killed. All were examined post mortem together with suitable controls. As lower concentrations of ethylene dichloride either killed animals more rapidly than trichloroethylene, or the extent of damage found at autopsy was greater, the conclusion was reached that the former is more toxic for rabbits than the latter. However, it was emphasized that the general order of toxicity was not greatly dissimilar.

It is not known that the results of these experiments will be published. Correspondence with the department at Columbus, Ohio may lead to these records becoming available. Since this was a matter of litigation, it is likely that conflicting testimony may have been presented, which also will appear in hearing records.

INFILTRATION ANESTHESIA FOR CURETTAGE OF UTERUS

To the Editor—Please describe a method of carrying out direct infiltration anesthesia for curettage of the uterus. You mentioned it under Herpes After Spinal Anesthesia for Curettage. Please omit name.

M D, Ohio

ANSWER—The patient should be given a hypodermic injection of 16 mg of morphine and 0.3 mg of scopolamine about forty five minutes before the infiltration is to be begun. The narcosis due to morphine persists for a variable length of time after the operation is ended and this usually insures that the patient will sleep or at least be comfortable for some time after the operation.

The surgical preparation of the vagina is, of course, the same as when inhalation anesthesia is employed. The patient should be made as comfortable as possible during the operation. Hence abundant pillows should be placed on the operating table, especially under the back and around the shoulders where braces are usually applied. For the local anesthetic, 0.5 per cent of procaine hydrochloride is used. To this solution after sterilization, two drops of 1,000 epinephrine are added for each ounce. About 175 cc of solution is prepared.

The technic for dilation and curettage is as follows. A narrow retractor is used to depress gently the posterior vaginal wall. If the patient has a narrow vagina or a rigid perineum solution should also be injected into the perineum as follows. The needle is inserted about midway down one labium majus and solution is injected all along the edge of this labium, then across the fourchette and up the edge of the other labium majus. It is usually necessary to remove and reinsert the needle a few times, but one must always reinsert the needle in an area that has already been infiltrated. With Allis forceps, slight traction is then made on the infiltrated fourchette and solution is injected into the layer between the vaginal wall and the rectum not only in the median line but also well out to the sides in the shape of a fan. The needle is inserted about 5 cm in each direction, and about 30 cc of solution is distributed in this space. In some cases it is necessary to insert the needle deeply through the fascia over each levator ani muscle and inject about 10 cc of solution into the muscles and fascial layers. Then the cervix is grasped with a tenaculum and gently pulled down and to the right side. The needle, which should be long and flexible, is then inserted into the left parametrium by following closely along the cervix for a distance of from 2 to 3 cm. If any resistance at all is met the needle has most likely penetrated the cervix. In this case it should be pulled back slightly and then inserted a little more laterally. After the needle is in the parametrium, the plunger should be pulled up slightly to make certain that the needle has not entered a blood vessel. If no blood appears in the barrel of the syringe, about 10 cc of solution is injected slowly and with the needle constantly but gradually being withdrawn. The same procedure is carried out on the right side of the cervix. The procaine hydrochloride in the parametrium blocks the large sympathetic ganglions of the Frankenhäuser, which are situated at the upper portion of the cervix. The local anesthesia produces blanching of the vaginal mucosa round the cervix. If parts of the vaginal epithelium are not blanched, it is best to inject about 5 cc of solution into the space between the cervix and the bladder and between the cervix and the rectum. It is a good plan to administer a hypodermic

injection of solution of pituitary when the operation is begun in order to insure a minimal loss of blood from the uterus

After waiting about five minutes it will be found that the cervix is soft enough to permit easy dilation without pain. Curettement is likewise a painless procedure and there is little bleeding. The uterus returns its tonicity even if solution of pituitary is not used. Occasionally the patient experiences slight pain when the corners of the uterus are curetted. One should not undertake to curet the uterus without a thorough knowledge of its anatomy or without an understanding of pathologic conditions that may be present.

TALIPES EQUINUS VARUS

To the Editor—I have an infant patient now nearly 2 months old whom I have been treating since birth for congenital talipes equinus varus. At the outset I utilized fixation and overcorrection simply by strapping with adhesive plaster. For the past month I have been using a metal splint which I remove at frequent intervals and massage the extremity. At this time there is evident improvement. How long should this treatment be continued? Would a plaster cast be more advisable? I want to avoid atrophy of the leg muscles. Can my present treatment be improved and what is the prognosis where early treatment is employed? Please omit name.

M D Illinois

ANSWER—Improvement must be continued until overcorrection is obtained, until the foot can be put in the overcorrected position by a moderate amount of pressure by the surgeon's fingers holding the leg just above the ankle and gently forcing the foot in the overcorrected position by the application of the index finger. A plaster-of-paris cast would undoubtedly be more advisable, but it should be applied by a trained physician, preferably an orthopedic surgeon. The present treatment can be improved by calling an orthopedic surgeon in consultation. If no additional measures are necessary, assurance can be felt that everything possible is being done for the patient.

The prognosis in congenital talipes is excellent, depending on (1) early diagnosis, (2) early treatment, (3) persistent treatment and (4) cooperation of the surgeon, parents or nurse, and later of the patient. Overcorrection should be obtained and maintained until functional use (walking in the overcorrected position) makes the correction permanent.

SIMULTANEOUS IMMUNIZATIONS

To the Editor—Can one administer all the toxins and antitoxins and vaccines at the same time? (I am referring especially to such as the scarlet fever toxin, diphtheria toxoid, vaccination against smallpox and prophylactic pertussis vaccine.) Can there be any more harmful symptoms or complications from the administration of all these vaccines and serums at one sitting than by injecting each at a time?

JACOB STERN M D Chicago

ANSWER—There is no experience with human beings on the basis of which a definite answer can be given to these questions. It is not known for instance whether successful vaccination against smallpox would interfere in any way with the immune reactions against scarlet fever toxin, diphtheria toxoid or pertussis vaccine. Neither is it known whether the inoculations mentioned would cause more serious symptoms if made at one time than if made at different times, but it would seem reasonable to assume that simultaneous inoculations might give rise to serious disturbances. Certainly it would not be advisable to undertake simultaneous inoculations in the present state of knowledge and experience.

HYDROCYANIC ACID EFFECTS ON PARKINSONISM

To the Editor—I have under my care a man aged 44 with a definite history of epidemic (lethargic) encephalitis in 1924 and parkinsonism developing five years later. For fifteen years he has been engaged in fumigation with hydrocyanic acid and states that whenever he has a whiff of the gas there is an increase in his rigidity. He is now being forced into retirement and desires to establish an industrial connection. I would appreciate information and special references concerning the effect of hydrocyanic acid in aggravating a condition quite obviously caused by an infectious disease. Please omit name.

M D District of Columbia

ANSWER—Hydrocyanic acid, being an internal asphyxiant and thus a disturber of normal tissue oxidation theoretically may be regarded as a temporary accelerant of almost every disease. The following quotation is derived from Henderson and Haggard's 'Noxious Gases' (New York Chemical Catalog Company, Inc, 1927):

'The tissues manifest life by heat and movement and the continual oxidation of foodstuffs. Cyanides stop this oxidation and the vital functions are suspended. The suspension is maintained only during the presence of the cyanide. Its removal allows the return of normal function if death has

not occurred during the period of oxygen starvation. Cyanide poisoning is a form of asphyxia caused by the arrest of internal respiration.'

In unprejudiced fairness, doubt may be entertained that the severity of Parkinson's disease and residual encephalitis is measurably increased by an occasional whiff of hydrocyanic acid. Even if at the moment of exposure the manifestations of these disorders are more noticeable, the effects of the episode are not known to eventuate in a persistent aggravation of the preexisting diseases. General discussions of the nature of hydrocyanic acid poisoning may be found in Alice Hamilton's 'Industrial Poisons in the United States' (New York, Macmillan Company, 1929), Kober and Hayhurst's 'Industrial Health' (Philadelphia, P. Blakiston's Son & Co, 1924), and several official publications of the United States and the British public health services.

USE OF DIPHTHERIA TOXOID

To the Editor—In November the local Parent Teachers Association sponsored and carried through the inoculation of 281 children of school age with the first of two treatments for diphtheria with toxoid. During the entire fall more or less trouble occurred with bad throats and in several cases this was followed by glandular trouble. Sore throat with fever occurred before the inoculation but so far as I know there was no nephritis. Thursday December 14 a youth aged 18 years who received the first treatment on November 29 was taken to the local hospital with acute nephritis. So far as I am able to find he was not ill with a bad throat any time this fall. I am wondering what the history of toxoid is with reference to nephritis. Would there be justification for concluding that his illness is due to the toxoid or might there be some other cause? I am wondering if it would be asking too much of your office to answer my questions at once and rather fully. As a school superintendent I am intensely interested in health and if nephritis is apt to follow inoculation with toxoid I don't want to be urging that it be taken. I would appreciate knowing what the picture is relative to diphtheria and toxoid and toxoid and its after effects.

Superintendent West Union
Public Schools

E A RALSTON West Union Iowa

ANSWER—While the possibility that the illness of the boy may have been due to the toxoid cannot be excluded absolutely, it seems probable that it resulted from some other cause. The experience in immunization against diphtheria does not indicate that nephritis is likely to follow the injection of toxoid. Toxoid properly administered appears to be an effective means of preventing diphtheria without any serious disturbances.

REDUCTION OF LOCAL ACCUMULATIONS OF FAT

To the Editor—An attractive woman aged 28 has appealed to me for scientific information that she may use to effect a reduction in the size of the calves of her legs. She is of slightly less than average size and is well proportioned except for an accumulation of fat around the thickest portion of the gastrocnemius muscles. The basal metabolic rate is normal and there is no evidence of any glandular abnormality. Five months ago she had a suspension operation for retroversion of the uterus. As a young girl she was very active in dancing, skating and rope jumping and the muscles of the legs are quite well developed. There is no tendency toward any deposit of fat elsewhere than the region mentioned. Is there anything in the way of massage or exercise that I may prescribe for her? If so please give details. Kindly omit name.

Jr Virginia

ANSWER—The reduction of local accumulations of fat is a difficult and uncertain matter. The use of a mild weight reduction diet accompanied by exercise of the affected parts is sometimes successful. Dancing and rope skipping would be the exercises of choice. Since the patient is not overweight, the reduction diet should be intermittent so as not to cause too much general weight loss. The exercises, however, must be maintained indefinitely, since there appears to be an increased tendency for the deposition of fat around well developed muscles once the exercise of those muscles ceases. The latter observation may have some bearing on the etiology of the fat accumulation in the case described.

VISUAL EFFICIENCY

To the Editor—I cannot get quite clear in my mind what a supervising approver for an insurance company means when he states that 20/100 vision is equivalent to 48 per cent of visual efficiency—based on a chart furnished by the American Medical Association. The vision in one eye of the patient in question is light perception and light projection and in the other eye is 20/100.

LEO J GOLDBACH M D Baltimore

ANSWER—The Section on Ophthalmology of the American Medical Association in 1925 received a report of a committee appointed to determine the percentage of loss of vision due to industrial accidents. This report is published under the title

of "Appraisal of Loss of Visual Efficiency" by the American Medical Association and is obtainable by purchase (ten cents)

According to that table, when the vision for distance is 20/100 and for near 14/70, by the Snellen scale, the percentage of visual efficiency in that eye is 48.9 and the percentage of loss of vision is 51.1. The Wisconsin table, which is in use by the industrial commission of Illinois, allows 75 per cent loss of vision or 20/100 vision

TOXIC NEURITIS OF OPTIC NERVE

To the Editor—I have a case of evidently toxic neuritis of the optic nerve of a hair dresser who has been using benzene Vapron shampoo and Inecto-Notox hair dye. I should like to know whether there is any record of toxic neuritis from these chemicals and if so where I could find information in the literature as to the treatment of such cases. Also chemical analysis of ingredients in the dyes.

C. S. BUCHER, M.D., Champaign, Ill.

ANSWER—There are no reports in the literature to the effect that Vapron or Inecto-Notox hair dye has caused optic neuritis. Naphthalene has a powerful effect on the lens of lower animals and when ingested produces cataract. Methyl alcohol fed to animals produces a degeneration of the macular ganglion cells of the retina. Clinically, retrobulbar neuritis is found in various poisonings, including methyl alcohol, tobacco and diabetes. Optic neuritis from benzene has not been heretofore reported so far as can be learned.

PRESCRIPTION OF DIURETICS

To the Editor—Please suggest how one may prescribe the diuretics urea, ammonium chloride and ammonium nitrate in a palatable form.

A. J. REICH, M.D., New York

ANSWER—The following prescriptions yield preparations probably as palatable as may be. All of these contain 1 Gm. of the drug per teaspoonful, which must be well diluted with water before being taken.

Rx Ammonium chloride	30 Gm
Anise water	30 cc
Syrup of glycyrrhiza	to make 120 cc
Rx Ammonium nitrate	30 Gm
Syrup of glycyrrhiza	to make 120 cc
Rx Urea	30 Gm
Acacia powder	12 Gm
Syrup of cinnamon	to make 120 cc

DIARRHEA AFTER TAKING IRON PREPARATIONS

To the Editor—The editorial entitled "Available Iron in Therapy" (THE JOURNAL, Dec. 30, 1933, p. 2123) states that the iron in pyrophosphate not only is available but is held in such firm combination that it does not produce the astringent effects so characteristic of other iron salts. Astringent effects are local. Astringent salts are used to curb diarrhea. Large doses of iron and ammonium citrate say from 6 to 8 Gm. daily induced loose stools or even diarrhea so that the dosage has to be curtailed. I never quite understood why this is so. The prevailing opinion among the profession is that iron is constipating as it is in the small dosage that many employ. Can you explain?

THOMAS I. O'DRAIN, M.D., Philadelphia

ANSWER—Iron and ammonium citrate is not a protein precipitant and hence is nonastringent. The laxative effect of the large dosage mentioned may be due to irritative action of the drug in such doses or to its otherwise disturbing digestive equilibrium. It is in this manner, no doubt, that large (1 Gm.) doses of reduced iron, which by itself is incapable of producing irritation, may cause diarrhea.

TYPHOID VACCINE AND TETANUS ANTITOXIN

To the Editor—1. Should a patient who has taken her last prophylactic dose of typhoid vaccine five days previously receive tetanus antitoxin for a moderately deep lacerated wound of the leg? The wound was inflicted by a metal support under a card table and occurred two days before the patient was seen. There is apparently little infection and no sutures were required. 2. Would the fact that the patient had just received a dose of typhoid vaccine increase the danger of reaction from the administration of tetanus antitoxin? Please omit name and address.

M.D., South Carolina

ANSWER—1. There seems to be no good reason why the patient should not be given tetanus antitoxin without delay if the nature of the wound demands antitetanus prophylaxis.

2. The typhoid vaccine would not, so far as is now known, increase the danger of reaction from tetanus antitoxin.

SAFE ANESTHETIC FOR OFFICE USE

To the Editor—What do you regard as the safest anesthetic for short anesthesia in office work? The general practitioner is in need of a safe anesthetic for minor office work such as opening boils, curetting ulcers, puncturing ear drums and things that require only a moment or two of work. Ether takes too long to be effective and I have always been just a little afraid of chloroform. I have given ethyl chloride a few times but I think it is unsafe in fact some claim that it is highly toxic. Is there anything safer? Or it may be that I am just a little too apprehensive in regard to the different agents. Please omit name.

M.D., West Virginia

ANSWER—The local anesthetic procaine hydrochloride is the safest agent for minor operations in the office. There are, however, many minor operations, such as those mentioned, in which a general anesthetic is desirable. The safest general anesthetic for office use is, no doubt, nitrous oxide, as has been amply demonstrated by its use in dental offices. Certainly, chloroform is to be avoided, and ethyl chloride is unsafe unless it is administered by an expert anesthetist. The safest possible agent is the only one permissible for office use, as a fatality due to an anesthetic used for a minor operation would carry with it great moral, ethical and medicolegal responsibility.

THYROID DISEASE IN A CHILD

To the Editor—The thyroid gland has been enlarging gradually in a girl aged 4 years. The child has a slender neck and one can see distinctly a small swelling corresponding to the thyroid gland. The mother had an enlarged thyroid gland with some symptoms of thyrotoxicosis while carrying the child. The girl is quite excitable. What management would be proper at the present time? Would compound solution of iodine in minimal doses be indicated? Please omit name.

M.D., Iowa

ANSWER—The management of thyroid disease in children is essentially the same as in adults except that more conservatism is indicated. The metabolic rate should be determined in a qualified laboratory. Growth and nutrition should be observed. Iodized salt should be used in the cooking and at the table. Cod liver oil given for vitamin content will also supply iodine. Together these substances will cover the iodine requirements. Foci of infection in the teeth, nose and throat should be removed. The daily life should be quiet and restful.

DOG AS A CARRIER OF SCARLET FEVER

To the Editor—Have dogs ever been known to act as carriers of scarlet fever and to transmit the disease to human beings? What is the public health teaching regarding a dog in a house quarantined for scarlet fever? Is the dog allowed to run free or should he be kept on the premises? Please omit name.

M.D., Minnesota

ANSWER—There is no evidence to indicate that the dog can be anything more than possibly an accidental carrier of scarlet fever. Dogs, like other household pets, must be excluded from the sickroom and from contact with patients suffering from acute infectious diseases. When thus excluded, it would seem to make little difference whether the dog is allowed to run free or is confined to the premises.

GLYCERITE OF BISMUTH BY MOUTH IN SYPHILIS

To the Editor—I should like to inquire as to the efficiency of the oral administration of the glycerite of bismuth in doses of 20 minims (1.25 cc.) three times a day in the routine treatment of syphilitic cases and as to whether it is possible to use this medication to replace completely the intramuscular injection of bismuth. Please omit name.

M.D., California

ANSWER—Glycerite of bismuth in any dose is of no value as an antisyphilitic. Administration of bismuth salts by mouth has been tried by Levaditi and others on syphilitic rabbits with inconstant results, far inferior to the results of intramuscular injection.

ACNE

To the Editor—Please inform me concerning the best line of treatment of pitting and scarring in acne.

F. L. CHENAULT, M.D., Decatur, Ala.

ANSWER—The major portion of methods of treatment of pitting and scarring in acne are of little or no value. The so-called peeling methods not infrequently increase rather than diminish the disfigurement. With proper hygiene of the skin in general pitting and scarring gradually improve with time and radical intervention is usually not justified.

EFFECTS OF IODIZED SALT

To the Editor—Please tell me what the effect would be in the use of iodized salt over a long period of time in a patient who has a basal metabolic rate of —23. How would this affect the giving of thyroid? Kindly omit name
M D Illinois

ANSWER—The prolonged use of iodized salt would not lower the rate of a patient to —23 per cent and, on the other hand, might affect the patient's thyroid so that a gradual rise of metabolism toward normal might occur. It would not affect the giving of thyroid if this is indicated. If thyroid disorder, either with or without goiter, is thought to be present, iodized salt is indicated.

CONTINUOUS USE OF QUINIDINE

To the Editor—Will you please advise me regarding reports on long continued use of quinidine in good sized doses. It seems to me that I recently read a report of 12 grains (0.78 Gm.) of quinidine being used daily over a period of months.

GEORGE W JONES M D Clovis N M

ANSWER—Patients with whom it agrees may be given such doses of quinidine indefinitely. It has been given for a year, and even for years.

ACUTE INFECTIOUS MONONUCLEOSIS

To the Editor—Is there at present a specific for use in the treatment of acute infectious mononucleosis or is the treatment entirely symptomatic?

J M BODENHEIMER M D Shreveport La

ANSWER—There is at present no specific treatment of acute infectious mononucleosis. Fortunately, symptomatic treatment is usually successful.

INFECTION WITH TUBERCULOSIS

To the Editor—In Queries and Minor Notes in THE JOURNAL February 17 the statement is made that an individual who was once infected with tuberculosis to the extent that he reacts positively to tuberculin is rendered hypersensitive to further tuberculous infection in a manner similar to that of an individual who is allergic to ragweed pollen. While such a theory has been promulgated by some writers the majority of workers in this field still maintain that a slight tuberculous infection reduces the risk of further infection.

In a recent paper (THE JOURNAL April 8 1933 p 1077) C A Stewart of Minneapolis reports his observations on eighty-four children at the Lymanhurst School for Tuberculosis and from his studies he concludes that an individual who has a primary tuberculous infection is doomed thereafter to develop consumption if successfully reinfected from exogenous or endogenous sources.

Of course no one doubts the fact that an individual cannot develop tuberculosis as a result of an endogenous infection unless he has previously been infected with tuberculosis and a focus containing viable tubercle bacilli is still present somewhere in his system. But there is no sufficient evidence to warrant the contention that a person who once had a primary tuberculous infection is more likely to be reinfected from exogenous sources.

This is not the place to discuss in detail the theories advanced by Dr Stewart and his associates nor is it necessary since no less an authority than Dr William H Park (THE JOURNAL Nov 18 1933 p 1619) discusses this matter in detail in connection with his report on the use of BCG vaccine and he and his collaborators conclude: "We do not think that slight primary tuberculous infection acquired by natural infection or produced by vaccination diminishes resistance against future superinfections by tuberculosis."

It is a matter of common knowledge that from 75 to 90 per cent of the adult population especially in urban centers have had a primary tuberculous infection as indicated by a positive tuberculin reaction yet only a small percentage develop clinical tuberculosis. If a primary infection would render an individual hypersensitive to further infection the incidence of tuberculosis would be much larger than it is. It may be argued that the greatest number of allergic individuals escape tuberculous disease because they are not exposed to infection. It is reasonable to suppose however that taking the population at large individuals who have had a primary infection are just as much exposed as those who have never been infected so that if there is sufficient infection prevalent among the population to produce a primary infection in such a large percentage of people one would expect sufficient exposure to reinfection to produce disease in a larger percentage than actually occurs. One is therefore forced to the conclusion that the vast majority of allergic individuals have sufficient resistance to ward off reinfection.

EFFECTS OF BODY TEMPERATURE ON SPERM

To the Editor—In Queries and Minor Notes in THE JOURNAL March 17 page 866 Dr G L Moench stated that the body temperature alone other factors remaining the same will kill all sperm in the female genital tract within twenty-four hours and certainly within forty-eight hours. If body temperature alone killed sperm living sperm in ejaculations from twenty-one to twenty-eight days after bilateral complete vasectomies would not be observed. However living sperm have been found after vasectomies in this time interval as reported by Dr A Elmer Belt (THE JOURNAL February 3 p 396).

Montana April Report

Dr S A Cooney, secretary, Montana State Board of Medical Examiners, reports the written examination held in Helena, April 4-5, 1933. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. Two physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year	Per
		Grad	Cent
Northwestern University Medical School		(1929)	83.5
Sch of Med of the Division of the Biological Sciences		(1932)	81.4
University of Illinois College of Medicine		(1931)	79.5
Washington University School of Medicine		(1932)	82.1

Book Notices

Speech Disorders A Psychological Study of the Various Defects of Speech By Sara M. Stinchfield Ph.D. Lecturer in Psychology University College University of Southern California Speech Clinic Orthopedic Hospital School Los Angeles Cloth Price \$4 Pp 341 with 26 Illustrations New York Harcourt Brace & Company London Hegan Paul French Trubner & Co Ltd 1933

This carefully written volume will be of chief interest to the psychologist but of little interest or value in the treatment of speech disorders. To the person with speech defect it will appeal as a scientific book with interesting statistics, but no cures will be effected by the reading. Speech in infancy and childhood is tabulated with numerous relationships, but a too technical classification is presented. The deaf, blind and cleft palate child is discussed from a social point of view. References are numerous, but page numbers often are not mentioned. The pages on stuttering are devoted to etiologies but no final conclusion is reached. Outgrowth as a treatment is spoken of unfavorably, but no idea is given as to the best treatment for the defect. Freud's treatment is discussed but not evaluated. A comparison is made between college and school groups as to number and kind of speech defects. The author discusses researches on right and left handedness and on cerebral dominance made by different speech specialists and finds that there is no evidence that either of these theories gives the etiology. One chapter is taken up in comparing the scholarship and aptitudes of groups of students in college and school in relation to their being silent and oral readers in their study. Five excellent charts are shown with this information but the reader wonders what this has to do with speech disorders. The speech tests given are confined entirely to school and college groups but not to business or social groups. The chapter on case histories is good. Bluemel is given credit for "the most lucid and detailed" form of treatment. The author is mistaken in calling his theory visual amnesia. It is decidedly auditory. Bluemel (vol 1, p 377) refers to "auditory amnesia as the primary cause of stammering." The author is also mistaken about the Swift method. Swift, the originator of the visual theory and the treatment of visual development, says "the cause is visual asthenia" (*A Psychological Analysis of Stuttering Journal of Abnormal Psychology*, October-November 1915 p 13, line 3). Also in "Speech Defects in School Children and How to Treat Them" (Boston, Houghton Mifflin Company, 1918, p 18, line 10), 'they constantly lack this visual image while they are stuttering'.

The whole book is well written and clear to those familiar with speech nomenclature, but poor as far as treatment for stammering or other speech defects are concerned. In other words the author gives a psychologic study of all phases of the subject except the psychologic study of treatment which is the most important phase of the whole subject.

Diagnostics urgents Abdomen Par H. Mondor professeur agrégé à la Faculté de Paris. En deux volumes. Second édition. Cloth Price 160 francs Pp 1064 with 306 Illustrations Paris Masson & Cie 1933

In this edition the author offers an exhaustive differential diagnosis of acute abdominal conditions without consideration of pathogenesis or therapy. The book contains chapters on acute peritonitis, traumas of the abdominal cavity, intraperitoneal hemorrhages, intestinal occlusion, other syndromes such as acute dilatation of the stomach, acute hemorrhagic pancreatitis, intestinal infarcts, torsion and volvulus of the intestine. Discussion of differential diagnosis is exemplified by case

histories accompanied by temperature charts. Owing to the presence of many repetitions, several chapters are rather voluminous, 127 pages being devoted to the diagnosis of appendicitis, 89 to perforation of gastric and duodenal ulcers and 41 to Meckel's diverticulitis. While discussing appendicitis, the author applies the term "absurd" to a diagnosis of acute enteritis or spastic colitis. Reproductions of photographs are instructive but not attractive, because of a grayish appearance caused probably by overexposure. Certain omissions have been noticed for instance, in the discussion of the diagnosis of ectopic pregnancy, the Aschheim-Zondek test is not mentioned at all, blood chemistry has not been considered in the diagnosis of intestinal occlusion. Generally speaking, physical and also roentgenographic observations are described meticulously, while laboratory observations have been completely disregarded or are treated in a stepmotherly manner. The index of authors mentioned in the text appears to be superfluous as no bibliographic references are given. The book is well written, it contains an immense wealth of diagnostic material and may be considered as a valuable and authoritative contribution to the French medical literature.

Red Medicine Socialized Health in Soviet Russia By Sir Arthur Newsholme K.C.B. M.D. and John Adams Kingsbury LL.D. Secretary of the Milbank Memorial Fund. Cloth Price \$2.50 Pp 324 with Illustrations Garden City N.Y. Doubleday Doran & Company Inc 1933

Red Medicine is both interesting and evasive. It is interesting in that it carries the reader a little too smoothly and altogether too hurriedly over a vast area of perhaps heretofore slightly known territory. Too smoothly, because the reader is likely to be impressed with the apparent ease with which each item of interest and every incident of note seem to have been discussed with more or less intimate understanding and sang froid, too hurriedly because in the limited time of possibly six weeks the reader is carried rapidly over 9,000 miles of southwestern Soviet Russia, through and about fourteen cities, in a section of the world where some familiarity with the language, customs and previous social system would, no doubt, have been of great assistance in checking the interpreter's explanations. This trip must have been much less deliberate than that of the original Volga boatmen.

The style of the book is simple and the reader is somewhat intrigued by the freely flowing accounts of night life, dancing, bowling, high spots of industry, commerce, agriculture, building operations and public parks and the authors' side trips to view famous jewels and objects of art. Indeed, the first part of the book is an interestingly written travelogue of a previously planned, personally conducted sightseeing trip into hitherto unknown parts. One's interest tires, however, on account of the too free use of superlatives in praise of services and institutions that must have been hastily observed. Eleven chapters are devoted to a description of communism, government in the Union of Socialist Soviet Republics, industrial conditions and health, agriculture, religious and civil liberty, home life recreation clubs, education women in Soviet Russia, marriage and divorce.

Those chapters which are devoted to care of children care of maternity, the problem of abortion, the training of physicians the medical care of the sick in residential and nonresidential institutions and care of tuberculosis and venereal disease are filled with references to institutions and generalities concerning the mechanics of medical care and organization details.

The discussion of medical education is inadequate and unconvincing. The use of statistics on pages 203 and 212 is inadequate for the purpose and the conclusion that 'evidently there has been a marked reduction in it' (infant mortality) is a dogmatic statement not supported by facts.

One looks in vain for an evaluation of the quality of medical care or an account of actual medical procedures. The authors have carefully and completely avoided a satisfactory discussion of the income of physicians and the methods by which they are paid.

The treatment of the entire subject is exceedingly favorable to the forms of medical institutions that the authors found on this trip. In spite of the fact that the authors feel that they took precautions against drawing conclusions from "show window display" there are many reasons to think that they saw only the best of everything.

It is repeatedly stated that the Russians started from almost nothing in the way of medical care for the people (p 269), and it is recognized that this gave certain advantages, since there were no institutions to be changed or with which to compare present standards of medical care. Yet there is no adequate comparison of present-day medical practice with that of the prewar period.

The comparisons with the United States (pp 271-277) have some defects. The shortage of physicians in the rural areas in the United States seems to be exaggerated and belittled as due wholly to historical causes in Russia. Self medication, which prevails so much in the United States, is absent in Russia but only, according to the statements of the authors, because of the excessive price of drugs and their almost complete absence from private trade (p 274). The information on the income of physicians in Russia is extremely indefinite, and nowhere are definite figures given (pp 250-251 and p 274).

There seems to be a tendency to exaggerate the value of institutional medical care through laboratories, groups, hospitals and sanatoriums.

Much is made of the fight on cholera and typhus, but there is little reference to the fact that these have been abolished elsewhere and that the reduction in typhoid, diphtheria, small-pox and other diseases has been much greater in other countries.

Much is made of the fact that the lack of physicians was the cause of bad conditions previously, but nowhere is there a conclusion drawn that the increased supply of physicians might have produced improved conditions without the excessive socialization.

The lack of food and housing is mentioned, but little stress is laid on the fact that the first of these especially has been the cause of tremendous famines that have undoubtedly caused more deaths than disease.

While there is frank reference to the abolition of all essential liberties, there is no discussion of how this must affect medical research, especially in its social relations. It is hard to believe that scientific research can flourish in such an atmosphere.

Medizinische Kolloidlehre Herausgegeben von Prof Dr L Lichtwitz Direktor der I Inn Abt des Rudolf Virchow Krankenhauses Berlin Dr Dr Rapp Ed Liesegang und Prof Dr Karl Spiro Direktor des Physiologisch Chemischen Instituts der Universität Basel Lieferung 3 [Untersuchungsmethoden] Paper Price 5 marks Pp 153 232 with illustrations Dresden & Leipzig Theodor Steinkopff 1933

This instalment of *Medizinische Kolloidlehre* deals chiefly with fermentations and the immunity reactions. Kurt G Stern, writing on the enzymes, discusses their chemical nature, their colloidal and their electrolytic character. He prefers the term "sorption" to "adsorption," as it is necessary to abandon the attempt to distinguish between mere physical and true chemical union, sorption being the result of difference in electrical potential. The kinetics and the character of enzyme reactions in solutions as well as within cells is discussed, and the chapter ends with an estimate of the number of enzyme molecules per cell. This is calculated for the yeast cell at somewhere between 15,000 and 50,000, while *Aspergillus niger* contains only 1,000 saccharose molecules. It is probable that the genes of genetics are catalyzers whose number per cell may be as low as 2, 1 or 0. Alfred Klopstock endeavors to show to what extent colloid chemistry can explain the antigen-antibody reaction. While all antigens are colloids, not all colloids are antigens. Antibodies may also be crystalloid. Ehrlich's fanciful theory of 'haptophore' and "ergophore" groupings with its great variety of antibodies must be abandoned and the unitarian view of Bordet and Friedberger adopted, which postulates a similar fundamental change that manifests itself in different forms under different conditions. These reactions are essentially of a colloid-chemical character. Thus, the toxin-antitoxin reaction is essentially a change in the colloidal nature of the toxin particles which may under certain conditions result in deflocculation. Anaphylaxis is the same kind of reaction involving antibodies that are present in or on the cells and which react with the antigen resulting in a change in the colloidal equilibrium of the surface layer. Whether this change directly acts as the functional stimulus or whether it results in the production of histamine which may be the direct cause of the symptoms (as is held of late) is merely a matter of detail.

Medicolegal

Insurance, Accident Death from Gas Bacillus Infection—On the life of Harry S Martin, the Bankers' Life Company of Des Moines had issued two life insurance policies, both providing for double indemnity if he died by accident. On April 28, 1930, Martin, a farmer, went into and out of his hog house several times, caring for a litter of newly farrowed pigs. An employee, who was assisting him, noticed once as Martin was coming out of the hog house that the back of his hand had been skinned and was bleeding. Martin wiped his hand with his handkerchief but continued at his work until midnight, when he returned home. The next morning his wife noticed that the area around the wound was puffed and swollen and of a purplish color. Martin worked as usual on that day, except that on his way home for lunch he consulted his family physician, Dr Besser, who also observed a peculiar discoloration around the wound. He cleaned the wound with green soap and put on an iodine dressing, gauze and a bandage. On the second morning following the injury, Martin returned to Dr Besser's office, the wound then looking more angry. In the afternoon of the same day he called on Dr Besser again, and the wound was dressed as before. The local condition improved and the wound was last dressed by Dr Besser May 3 or 4. But Martin, who had been an energetic active man, was observed after the injury to slow down. His color was pasty and ashy, he had a sleepy look, and his eyes appeared sunken. He moved sluggishly and continued thus indisposed.

On June 6, Martin again consulted Dr Besser, this time because of abdominal pain. Early the next morning Dr Besser was called and visited Martin at his home. But the pain continued and, three quarters of an hour later, Dr Besser was called again. At this visit he made a tentative diagnosis of acute appendicitis and advised Martin to go to the hospital. Martin's wife observed at this time eight or ten little spots on his back, of a purplish color, like his hand had been when it was hurt. At the hospital a blood examination showed a white cell count of 14,000. A consultation was held and the tentative diagnosis of appendicitis was agreed to. On the morning of June 7, at about 9 o'clock Martin was operated on. When the abdomen was opened the appendix was seen to be somewhat inflamed, but neither Dr Johnson, who was operating, nor Dr Besser, considered its condition sufficient to account for the symptoms. The appendix was removed, but Martin did not improve. On the fourth day after the operation, symptoms of intestinal obstruction appeared and a second operation was performed. The incision was made at the site of the previous operation. As the stitches were removed the wound gapped open, exposing dark-colored muscle described by Dr Johnson as black and crepitant. The intestines were distended and generally black, but the intestine near the site of the operation was the best part. There was considerable fluid in the abdomen. No bands of adhesion nor twisting of the intestines were found. The odor was somewhat characteristic, from sour to rancid, not a normal odor. The wound was closed with drainage. A diagnosis of gas bacillus infection was made and an injection of serum was given but Martin died June 12, after a few hours of apparent improvement.

The insurance company paid the basic insurance required by both policies but refused to pay the double indemnity due if Martin's death was caused by accident. Thereupon Martin's widow, the beneficiary of the policies, sued to enforce payment of the double indemnity, alleging that Martin died by accident.

All the medical witnesses for the plaintiff believed that the gas bacillus might remain dormant in the blood for several weeks or longer and then set up an active infection in a part of the body remote from the point of injury, through which the bacillus entered. Dr Besser believed that there was no pathologic condition to account for Martin's death other than gas bacillus infection. The defendant-insurer contended, however, not only that the evidence offered by the plaintiff did not show that Martin's death was due to infection by the gas bacillus or that his death could have resulted from such an infection incident to the accident of April 28 but that it did not show even that the injury to Martin's hand was accidental.

The insurer's medical witnesses contended that the infection might have resulted from some failure of technic in the course of the operation or from other causes, that no certain diagnosis of infection by the gas bacillus could be made except by a laboratory test, and that the testimony of the insurer's experts showed that infection arising from the gas bacillus must develop at or in proximity to the injury which the bacillus entered that the bacillus cannot be carried in the blood stream and set up infection at a point remote from the point of entry, and that infection from this bacillus always appears within a very short time after the entry of the bacillus and develops rapidly.

The trial court directed a verdict for the insurer and gave judgment in its favor. The plaintiff, the widow of the insured, thereupon appealed to the Supreme Court of Iowa.

The Supreme Court was unable to see the force of the insurer's contention that there was no direct evidence to show that Martin's death resulted from an accident. The testimony of the widow, the family physician and the helper employed on the farm of the insured eliminated from consideration any injury other than that of April 28, 1930. All physicians who testified for the plaintiff believed that the gas bacillus entered the wound then inflicted. Whether the evidence as to the facts on which their opinions were based was true, and how much weight should be given to the opinions themselves, were matters within the discretion of the jury. The insurer contended that the appendicitis and the resulting operation introduced a new and independent cause and that, even if death did result from infection by the gas bacillus, the operation contributed to and hastened the death and that therefore double indemnity was not payable. It appeared to the Supreme Court however, that the evidence adduced by the plaintiff was sufficient to make a case for the jury and that in directing a verdict for the defendant the trial court erred. The ruling and judgment of the trial court were therefore reversed.—*Martin v Banlkers Life Co of Des Moines (Iowa)*, 250 N W 220.

Workmen's Compensation Acts Tuberculosis of Spine Aggravated by Strain.—The plaintiff, while in the employ of the defendant, strained his back. He soon resumed work and continued at it for several months. His employer, the defendant, reported the accident to the department of labor and industry but reported it as noncompensable. Some months after the accident the plaintiff was found to be suffering from tuberculosis of the spine, pulmonary tuberculosis and tuberculosis of one testicle. The industrial commission held that the plaintiff had tuberculosis of the spine at the time of the accident but that it was not then disabling, that the accident injured the plaintiff's back in the region attacked by the tuberculous process, that an injury may aggravate a tuberculous process in the spine or cause it to flare up, so that disability results that the injury by accident Aug. 17, 1929, was the cause of the plaintiff's disability, and that the plaintiff had been totally disabled since Aug. 22, 1930. The department of labor and industry therefore awarded compensation. His employer appealed to the Supreme Court of Michigan.

The plaintiff's medical witnesses were of the opinion that the fact that he was able to work at hard labor for several months after the strain showed that the strain aggravated his tuberculosis of the spine and caused total disability. On the other hand, the defendant's medical witnesses believed that an injury sufficient to effect that result would have produced an intensifying of the disease such as to disable the plaintiff from labor within a month. The Supreme Court concluded, however that there was evidence supporting the finding of the commission and that therefore it was not for the court to review it. In passing on the contention of the employer that the plaintiff's disability was caused by tuberculosis of the lungs and throat, unconnected with the accident, the court called attention to the commission's finding. "The fact that plaintiff has pulmonary tuberculosis which is or may be disabling does not defeat his claim for compensation in this case, as the commission cannot speculate as to what percentage of his disability is caused by the pulmonary tuberculosis or tuberculosis of the throat and the Pott's disease aggravated by the injury."

The award to the plaintiff was affirmed.—*Heller v Consumers Power Co (Mich)* 250 N W 298.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Menstrual Disturbances in Pulmonary Tuberculosis—Hesselstine and Spear observed the significance of menstrual disorders in pulmonary tuberculosis in 148 state sanatorium patients. The study seems to indicate that patients comparable to these are likely to have an increased mortality incidence if amenorrhea develops especially late in the disease. An unexplained amenorrhea in young women may be the first symptom of phthisis. Menstrual temperature increase not exceeding 1 degree F, appears to be a better prognostic sign than no thermal increase. Hemoptysis and blood-streaked sputum at menstruation were not associated with a poorer prognosis than at other times. Dysmenorrhea appears more likely to occur in parous than in the nulliparous women yet its incidence seems to decrease with the advance of the disease.

Modification in Technic of Bell-Beutner Operation—In Falls modified technic of the Bell-Beutner operation the uterus is exposed, the tubes and ovaries are freed from adhesions and the advisability of leaving one or both ovaries is carefully considered. A wedge shaped incision is made in the uterine fundus down to the mucosa from side to side including the interstitial portion of the tubes but not the attachment of the round ligaments to the uterus. The wedge is from 1 to 2 cm. wide at the top depending on the size of the uterus. The round ligaments are pulled into the wedge-shaped wound left in the fundus of the uterus by inserting the needle with number 2 chromic catgut through the posterior lip of the uterine wound near its center. The point of the needle emerges

close to the mucosa of the uterus and about 2 cm below the cut edge. The needle is then passed through the broad ligaments just below the round ligament, brought back and inserted through the anterior lip of the uterine wound at about the same level as the stitch through the posterior lip. When this stitch is pulled taut, the round ligament is doubled on itself and drawn into the groove of the fundus of the uterus, which closes over on top of the ligament. Two additional interrupted sutures are placed through the fundus from the posterior to the anterior wall. The wound and the suture line in the uterus are completely peritonized, leaving only one knot of fine catgut exposed, as in the original Beutner technic. Postoperatively, these uteri are found to be held well up in the pelvis and to be freely movable, and there has been less complaint of disturbance of the bladder and backaches since the adoption of this modification.

Treatment of Sarcoma of Uterus with Bone Metastases—Blum reports the case of a large malignant sarcoma of the uterus (removed by hysterectomy) with multiple bone metastases. The roentgenograms indicate that credit for the patient's complete recovery must be given to Coley's toxins. The author thinks it is well worth while to attempt the use of these toxins in any similar condition although they should not be used to the exclusion of other recognized methods of treatment. Coley has never advocated using the toxins in cases that were operable except for a brief period in sarcoma of the long bones (endothelial myeloma) in the hope of saving the limb.

Acute Capsulitis of Cystic Degenerated Adenoma of Thyroid—According to Plummer and Broders acute non-suppurative inflammation in the capsule of a cystic degenerated or partially degenerated adenoma will cause painful enlargement of the adenoma. The acute symptoms are more or less transitory. In cases in which thyroidectomy is performed the

histologic evidence of such acute inflammation is frequently not recognized for the reason that (1) sections are not taken from the capsule of the adenoma for microscopic study, (2) or, since the inflammation may be confined to certain portions of the capsule, the sections may not be taken from the regions involved and, (3) even though the capsule is carefully examined, acute or subacute inflammation may have subsided before thyroidectomy is performed. Gross hemorrhage into the substance of a cystic degenerated adenoma of the thyroid does not usually cause enlargement of the adenoma. Acute inflammation in the capsule of a cystic degenerated or partially degenerated adenoma predisposes to gross hemorrhage into the substance of the adenoma, and therefore inflammation and hemorrhage frequently are associated. If enlargement of a cystic degenerated adenoma of the thyroid has occurred gradually for several hours or days and such enlargement has been accompanied by pain, one must assume that the enlargement is the result of acute inflammation. If enlargement of this type of adenoma has reached its maximum within a few minutes, accompanied by severe pressure or pain, it must be assumed that the enlargement is the result of hemorrhage and at operation recent blood clots will be found in the substance of the adenoma. Since the two conditions are frequently associated, microscopic evidences of acute inflammation are likely to be found in the capsule of the adenoma, and in these cases symptoms that must be attributed to the inflammation will be present also—pain of longer duration, accompanied by tenderness, local heat and possibly fever.

Exclusion Operation for Duodenal Ulcer—Steinberg used two series of animals for his experiments. Of the first series (twenty-three animals) twenty-one survived. These animals had a typical Finsterer modification of the second Billroth stomach resection with an Exalto shortcircuiting operation and the motor part of the stomach removed. Seven animals in addition to the foregoing procedure, were subjected to a kink distal to the anastomosis. None of the twenty-three animals developed an ulcer. In the second series of animals a typical Devine operation was performed with an Exalto shortcircuiting of the duodenal contents, and the motor part of the stomach was left in place. There were twelve dogs in this series, and six developed definite large chronic ulcers. In the remaining six dogs, no ulcers were found. A kink distal to the gastroanastomosis was performed in three animals all of which developed definite chronic ulcers. The von Eiselsberg operation should be abandoned. There is not sufficient clinical evidence to justify a definite expression of opinion on the results of the Devine exclusion operation. From the experimental work and theoretical and anatomic considerations this operation should influence the production of jejunal ulcers. The author's personal clinical experience in twelve cases with a typical Finsterer exclusion operation has been favorable.

Multiple Ganglioneuromas of the Skin—Montgomery and O'Leary report a case of multiple cutaneous nodules of the skin, which clinically suggested multiple xanthoma but which they believe to be a case of multiple ganglioneuroma with origin from the peripheral sympathetic nervous system. There was no histologic evidence of xanthoma in the early well developed and involuting lesions. They believe that the large pale staining cells which predominated in the early nodules presented the principal morphologic features of sym-

pathetic ganglion cells, namely, one or two prominent, densely staining nucleoli, five Nissl granules in the cytoplasm of the cell and multiple dendritic processes. Transitions between endothelial cells, histiocytes and the large pale staining ganglion cells were apparent histologically, this led some pathologists to regard the ganglion cells as histiocytes and the case as one of reticulohistiocytic granuloma. It is the authors' concept, however, that the histiocytes and the inflammatory and granulomatous changes seen in association with the ganglion cells are more satisfactorily explained as the results of a secondary process, which, possibly because of interference with the vascular supply, resulted in disappearance of the ganglion cells and spontaneous involution of the lesions. The presence of multiple cutaneous tumors composed chiefly of ganglion cells is probably best explained on the basis of a malformation.

Pseudo-Atrophoderma Colli—During the last five years Becker and Muir observed two women patients with a dermatosis which seems to be a clinical entity, and in the cases observed there were no physical abnormalities. The patients were young Jewish girls. Clinical examination did not verify the preliminary impression of atrophy. The histologic section from one case did not show definite atrophy, although O'Leary stated that epidermal atrophy was found in sections from one of his cases. Therapy for seborrheic dermatitis had no effect on the lesions in one case, and rather strong salicylic acid ointment did not improve the condition in another case. The designation "pseudo atrophoderma colli" is suggested for this condition. The appearance of the lesions was that of a pigmentedary disturbance suggesting vitiligo. The lesions appeared to be atrophic. On close inspection the apparently depigmented regions consisted of epidermis thrown up into tiny folds. When the skin was put under tension, the contrast between the shiny and the dull areas was less marked but was still visible and the dull areas were covered with fine scales. When traction was released, wrinkling was again apparent. While it was difficult to outline the individual lesions the shiny pseudo atrophic plaques seemed to be arranged largely in a vertical direction.

Sympathetic System and Pain Phenomena—Shaw points out that the sympathetic fibers may conduct afferent stimuli subserving common sensation after the extirpation of the somatic innervation, this function appears to develop gradually after removal of the spinal nerve supply. Sympathetic fibers convey impulses of pain in certain types of intractable neuralgia which are distinct from the conditions of pain conveyed by the spinal system. The sympathetic system acts as a control on the somatic sensory thresholds and the removal of this influence is followed by a temporary increase of common sensitivity. The anatomic sympathetic pathway in the cervicothoracic region contains spinal sensory fibers, the irritation of which might result in a composite type of neuralgic pain. Surgical ablation of the paraspinal ganglia will definitely cure the sympathetic type of intractable neuralgia through the removal of the mechanism of pain. Periaxillary sympathectomy will certainly relieve pain in similar conditions and the operation produces its results by the induction of an inhibitory phase through the radiation of molecular shock throughout the sympathetic neural circuit.

Absorption in Intestinal Obstruction—Best and his associates carried out experiments in the hope that definite conclusions might be drawn as to the rate and selectivity of absorption above and below an obstruction. In the group in which methylene blue (methylthionine chloride) is known to have been recovered from the urine after its absorption from the intestine, there was only a slight variation in time, which could be accounted for by the difference in the size of the animals and particularly by the variations in the amount of retained secretions above the obstruction. An animal with a smaller amount of intestinal contents above the obstruction would have a greater concentration of the dye, and absorption would probably be more rapid than in an animal with greater retention. In no case was the absorption more rapid above the obstruction than it was in the normal dog. When the dye was injected into the lumen below the level of the duodenal or ileal obstructions, the time of its appearance in the urine varied between fifty and seventy minutes, showing that there was no increase and only a slight decrease in absorption below the level of obstruction. The authors were unable to demonstrate any increase in the rate or selectivity of absorption above or below the level of obstruction. Their experiments suggest that there is no increase in the rate or selectivity of absorption above the obstruction, and this seems strong evidence that increased absorption above the obstruction cannot be the cause of death. Their experiments also tend to rule out the probability of increased absorption below the obstruction. They believe that it is within the realm of probability that death following intestinal obstruction is due to a failure of neutralization or buffer reaction to take place between the upper and lower intestinal contents in the lower part of the intestine. This need not be interpreted in terms of the development of a definite toxin but rather of a physiochemical reaction that usually takes place when the contents of the upper and lower parts of the intestine are permitted to intermix. With this phenomenon there occurs absorption or failure of absorption of a substance, which causes a disturbance not in accord with normal cellular function and incompatible with life. Clinically the authors' best evidence of this is the fact that an obstruction of the distal colon is compatible with life for some time. This may be explained by the fact that the intermixture of the upper and lower intestinal contents has already occurred above the obstruction and absorption has taken place. If the obstruction occurs above the distal colon, in the more active secreting levels and the absorption area death occurs earlier than in the case of a lower obstruction. Thus in a subject with an ileostomy, partial admixture and absorption have already taken place but with complete duodenostomy or jejunostomy this admixture and absorption have not taken place and death occurs much earlier in the latter than in the former condition.

Milk and Its Relation to Tuberculosis—In a study of 300 tuberculous children in Toronto Price found that 15 per cent of the extrapulmonary tuberculosis (e g bone joint lymph nodes kidney and skin) was due to the bovine type of

tubercle bacillus. Infection with the bovine type occurred most often in the region of cervical lymph nodes. All the patients infected with the bovine type of tubercle bacillus had used raw milk and resided outside Toronto. The clinical investigation indicated the alimentary route of infection. The majority of children infected with the human type gave a history of contact with human tuberculosis. The clinical investigation indicated the respiratory route of infection. Of 200 samples of unpooled raw milk examined, eight yielded tubercle bacilli on direct smear and guinea-pig inoculation. Of 100 samples of pooled raw milk, twenty-six yielded tubercle bacilli. Of 100 samples of the same milk, pasteurized none showed tubercle bacilli on guinea-pig inoculation. This observation is confirmed by the fact that not a single case of bovine tuberculous infection has been encountered in this generation of children raised on pasteurized milk in Toronto where pasteurization is compulsory and has been rigidly enforced since 1915.

Manganese Treatment of Schizophrenic Disorders—Hoskins treated nine schizophrenic patients with manganese chloride by mouth over a period of several weeks without detectable influence on the psychosis. Thirty patients were subjected to intramuscular injections of a colloidal preparation of manganese (0.32 per cent manganese) over an average period of forty-nine days with an average total dosage of 227 cc. Several representative metabolic features were investigated at the beginning and at the conclusion of the medication. The results of the latter study were convincingly negative as regards both the clinical and the metabolic conditions of the patients. These negative results suggest that beneficial effects claimed by certain earlier investigators may have been due to unintentional psychotherapy.

*Detailed Description of a Safe and Reliable Method for Closing Large Bronchi W E Adams Chicago—p 198

Abscess of Lung with Pleural Effusions—The association of a lung abscess with a pleural effusion seems to Sergent and Iselin to be much more serious than previous reports indicate. In eleven cases reported by the authors there were nine deaths. Five of these were seen after a thoracostomy had been performed by others, the operation being followed by a more or less marked aggravation of symptoms. In only two did a thoracostomy suffice to cure the empyema and the lung abscess at the same time. In five cases thoracostomy was unable to effect a cure. It produced an amelioration but the abscess continued to develop leading to death at an interval varying from six weeks to eight months. From an anatomic point of view these cases were characterized by a pleural pocket of small dimensions and from a clinical standpoint they took the form of a chronic pleural fistula with progressive impairment of general health. In four cases thoracostomy led to a veritable catastrophe: the abscess had been crowded into the depths by

a considerable pneumothorax. The pleural pocket was then of large dimensions and the clinical picture one of a pleural suppuration persisting in spite of good pleural drainage. All the patients died in from six days to six weeks. Treatment depends on the difficulty of recognizing the existence and the situation of the abscess and the frequent multiplicity of pus pockets, pleural as well as pulmonary. In encapsulated pleural effusions the relatively slow impairment of general health after thoracostomy leaves time to locate and open successively residual pulmonary or pleural pockets. In diffuse effusions the situation after thoracostomy becomes alarming so rapidly that subsequent operations are of considerable gravity. Treatment should bend its efforts toward prevention by unearthing an abscess under the purulent pleurisy that masks it and by draining it after the effusion becomes encapsulated.

Treatment of Pulmonary Abscess—Overholt applied clinically the principle of peripheral lung fixation and regional, extrapleural compression over an abscess area in three cases. Each patient had pulmonary suppuration to a sufficient degree to be wholly incapacitated and bedridden for a large part of the time. All were treated without the necessity of lung cauterization and external drainage. All patients were hospitalized a comparatively short period of time. In each case a sufficient period has elapsed since operation without recurrence of symptoms to warrant a preliminary report. The longest period of hospitalization for investigation and operation was five weeks. All patients were discharged with an intact thoracic wall and with their cough and expectoration reduced to minimal amounts. Follow-up studies have shown that continued and satisfactory improvement occurred in all, with disappearance of practically all symptoms. A sufficient length of time has elapsed to indicate permanence of the results. In the selection of cases for regional thoracoplasty, the necessity of ruling out foreign body and bronchiectasis has been emphasized. It is also important to demonstrate the adequacy of internal drainage. The choice of regional thoracoplasty in the surgical management of pulmonary abscess need not necessarily be limited, however, on account of uncertainty as to bronchial drainage. The formation of pleural adhesions and the collapse procedure can be carried out and, if there is failure to cure cauterization of the underlying lung can be resorted to later and external drainage provided. In other words, a less serious and less radical type of operation is proposed for surgically treating lung abscess, which may be sufficient to effect a cure.

Method for Closing Large Bronchi—The unsatisfactory results of others in attempting to occlude large bronchi experimentally by the silver nitrate technic has led Adams to describe the following method, which he has used more than 250 times with no mortality. Morphine, 0.015 Gm., and atropine 0.0004 Gm., per kilogram of body weight are given from one-half to one hour before bronchoscopy. With the animal secured in the dorsal position, a bronchoscope is introduced and passed down to the carina. The applicator consists of a number 8 gage iron wire with threads cut at one end, about which a small piece of absorbent cotton is secured firmly. A small firm swab is necessary to obviate the danger of the cauterizing agent running down into the air passages when the swab is applied to the bronchial mucosa. The danger is further obviated by pressing the swab against the mouth of the silver nitrate container after it has been saturated with a 35 per cent solution and rotating it to wring out as much of the solution from the swab as possible. If the bronchus to be occluded is small, the swab is simply thrust into it and held in place for about ten seconds. In larger bronchi, as the swab is brought firmly in contact with the bronchial wall, the applicator is slowly rotated, thus rolling it around the entire circumference of the bronchus. As it is being rotated, a to and fro movement is made as though one were massaging the surface. The bronchus is thus well cauterized, the white area standing out in sharp contrast to the normal pink mucosa. The cauterized area should be about 1 cm. in width and include the entire circumference of the bronchus. An applicator with a curved tip is of value in cauterizing upper lobe bronchi. Complete occlusion occurs in from ten days to two weeks, depending on the size of the bronchus. If one application does not produce complete occlusion of the bronchus, the procedure is repeated.

Sugar Tolerance in the Arthritic H A Nissen and K A Spencer Boston—p 13
Cardiovascular Review for 1932 P D White Boston—p 20

The Association of Diabetes and Tuberculosis—Root observed that the incidence of active tuberculosis in 1,121 diabetic necropsies was 28.4 per cent and in 51,705 nondiabetic necropsies 2.29 per cent. Since the association of the two diseases would be expected less than half as frequently as the incidence of tuberculosis alone, it follows that active tuberculosis occurred in diabetic patients at necropsy between two and three times as frequently as expected. Tuberculous infection in diabetic children as shown by skin tests and calcified tracheo-bronchial glands is more common than in Massachusetts school children, and the development of adult type pulmonary tuberculosis in a group of 750 children who developed diabetes before the age of 15 years was more than thirteen times as frequent as among Massachusetts school children. Among adolescent diabetic patients who developed the disease between the ages of 15 and 19 years, pulmonary tuberculosis occurred sixteen times as frequently as among Massachusetts high school students. Among 1,373 diabetic adults examined roentgenologically, active pulmonary tuberculosis was found in thirty-eight cases, or 2.8 per cent. Deaths from pulmonary tuberculosis among diabetic persons increased from 4.7 per cent of 342 deaths before June 1919 to 6.7 per cent of 1,503 deaths between Aug 7, 1922 and Nov 2, 1931 in spite of the decreasing tuberculosis mortality in the community. The factors of familial contact, race,

occupation, housing, poverty and alcoholism do not appear to explain the greatly increased incidence of pulmonary tuberculosis in diabetes

Treatment of Tumors of the Ovary—Taylor points out that the extent of treatment required in a given case of ovarian tumor depends on the following factors 1 The tendency to develop to a great size is an important consideration in deciding the first question of whether or not to operate Certain of the small, non-neoplastic cysts will remain relatively stationary or will regress, while others, such as the pseudomucinous cysts, will almost inevitably reach enormous proportions 2 The tendency to develop various complications, particularly torsion, represents a hazard of varying importance among the different types of even the benign tumors and under certain circumstances, is a reason against delay in operating 3 The tendency to bilateral development must be the chief guide in determining the advisability of limiting the operation in a given case to the removal of only one ovary 4 The frequency of the malignant transformation of benign tumors remains a disputed question Percentages, however, are offered in the literature based either on the cases in which malignant areas are found within otherwise benign tumors or on the proportion of the malignant to the benign growths among tumors of supposedly similar histogenesis

Cholesterol Its Relation to Mental Disorder—Duncan summarizes his seven years study of the relation of cholesterol in mental disease He observed that the blood cholesterol is lowered in certain general conditions affecting the organism as a whole (1) heightened emotion and quickened psychomotor activity (2) fever and (3) hyperthyroidism A factor common to all these is an increased metabolic rate Blood cholesterol is raised in apathy and diminished psychomotor activity and in subthyroidism In each of these conditions there is a diminished metabolic rate The properties of cholesterol are such that when the cholesterol in blood and tissues is lowered, an increase of the metabolic rate is to be expected when cholesterol is increased, diminished metabolism should result The analysis of actively growing tissue supports this view Therapeutically induced diminution of the blood cholesterol acts on the nervous system, in some cases at least as a stimulant causing increased mental activity Therapeutic raising of the blood cholesterol acts on the nervous system, in some cases, as a sedative causing diminished mental activity It is concluded that cholesterol is one of the controlling factors of cellular metabolism and that neurons are susceptible to quantitative changes of this substance in their environment

Barbituric Acid Narcosis Treatment by Insulin—Strom Olsen describes a modification of technic by which it was possible to eliminate dangerous toxic manifestations in

narcosis in which 2 cc of a barbituric acid derivative (sommifame) was given intramuscularly. This was sufficient to induce sleep. From then on an average of from 5 to 6 cc in twenty-four hours was administered to subjects in robust health—a quantity that was adequate for the production of a fairly deep narcosis. Injection at regular intervals is not advocated. Some persons may develop toxic symptoms after only a few injections. A large proportion of these symptoms are due to upset of carbohydrate metabolism of the liver and the heart by the narcotic, and the administration of insulin and dextrose is an integral part of the treatment and a rational method of prevention. In the author's forty-six treatments on forty patients, fourteen were not given dextrose or insulin, in fifteen dextrose and insulin were administered immediately on the appearance of ketonuria or other toxic symptoms, and in seventeen dextrose and insulin were given from the commencement of treatment. In the first group ketonuria developed in six instances and narcosis had to be cut short in five, in two on account of circulatory collapse and in three because of marked ketosis, drowsiness and vomiting. Of the remaining eight treatments, four proceeded normally, while in the other four smaller quantities of the barbituric acid were given to avoid complications. In twelve of the fifteen treatments in the second group ketonuria developed, while in the remaining three other toxic symptoms supervened. As soon as ketonuria appeared, from 5 to 15 units of insulin was given with the next dose of the barbituric acid, followed by the ingestion of from 1 to 1½ ounces (30 to 45 Gm.) of dextrose. The optimal dose of insulin varied from one individual to another. In the remaining three cases no ketonuria was evident, but other toxic symptoms developed. In the group in which insulin and dextrose were administered from the beginning of the course and tolerably large doses of the barbituric acid were given throughout none of the seventeen patients thus treated developed ketonuria except one, in whom it appeared on the sixth day. In this patient insulin was increased from 20 to 30 units daily and the immediate effect was the entire disappearance of ketosis during the remainder of the course. These patients remained singularly free from alarming symptoms, especially circulatory collapse and in no instance was narcosis prematurely discontinued. Other toxic symptoms that remained in abeyance were extreme drowsiness, cyanosis, coldness of the extremities and vomiting. Insulin seems to have no effect in preventing pyrexia, oliguria, albuminuria and leukocytosis, for these symptoms occurred with equal frequency in the three groups.

Hypoglycemia in Idiopathic Epilepsy—Muchlin investigated the blood sugar values of a series of epileptic patients in order to find whether hypoglycemia might not be the causative factor in idiopathic epilepsy. The author observed that epilepsy is associated with a low fasting blood sugar. The dextrose tolerance curve in epilepsy shows that the islets of Langerhans are overactive. Drugs that are beneficial in epilepsy raise the blood sugar level (except bromides, which reduce the irritability of the cerebral cortex). In the post-convulsive phase of epilepsy the immunity from fits is associated with raised blood sugar. Variations in the balance of the autonomic nervous system have little influence on the incidence of fits. Natural recovery from epilepsy is associated with the onset of hypo-insulinism.

Early Signs of Preeclamptic Toxemia—To obtain information regarding the order of appearance of the early symptoms and signs of preeclamptic toxemia and the relation of

the symptoms and signs to each other, Browne analyzed the records of 320 patients. The evidence brought forward shows that, whatever the cause of preeclamptic toxemia may be, it is something that can cause each of the signs and symptoms directly. That is, each sign and symptom, such as hypertension, albuminuria and edema, is due directly to the toxic agent, and each is produced independently of the other. Hypertension does not cause albuminuria or edema, nor does albuminuria cause edema or edema hypertension or albuminuria. The minor early symptoms, such as headache and sickness, also seem to be due to the direct action of a toxic agent rather than to the increased intracranial pressure of cerebral edema or to the vascular changes of hypertension. The author states that, if his observations and the conclusions based on them are correct, it will be possible to narrow considerably the field of investigation into the causation of preeclamptic toxemia. Several illustrations of this assertion will suggest themselves, but he presents only two. 1. It might be assumed that a possible cause of preeclamptic toxemia is the increase in the volume of the blood that takes place normally in pregnancy, combined with a lack of vasomotor correlation due to some defect, congenital or acquired, in the 'blood pressure restrainers' in the carotid sinus. But, although this might give rise to hypertension, many other clinical features would still remain unexplained. 2. Preeclamptic toxemia cannot be due solely to a blood pressure raising hormone such as epinephrine, for, while such a substance might, if present in sufficient quantities, give rise to hypertension, the hypertension would not cause the other characteristic clinical phenomena.

Alleviation of Pain in Labor—McIlroy and Rodway state that 560 primiparas delivered spontaneously were given sedatives and anesthetics during labor and delivery. During the first stage, morphine, with or without potassium bromide and chloral hydrate, were given. During the second stage of labor the anesthetic that gave the most favorable results was undoubtedly a mixture of gas and oxygen. During delivery in some cases the mixture was supplemented by chloroform or ether. It was found that a combination of potassium bromide and chloral hydrate in the first stage is a useful and safe sedative, especially in excitable and nervous patients, and it has no apparent effect in lessening uterine contractions. Vomiting is avoided by sipping the drugs dissolved in at least 6 ounces of water with dextrose or lemonade. Morphine is the most valuable of all sedatives. It is rare to find any adverse effect on the mother or the fetus. It is much safer than many of the toxic barbiturates now in use. Its effect is intensified and prolonged by giving it in a 50 per cent solution of magnesium sulphate. In many cases an alteration in the frequency or duration of uterine contractions was not noticeable. In some cases, the intervals between the pains were prolonged but the pains were increased in intensity. Observations on the effect of morphine on the infant showed that spontaneous respiration took place no matter how late the drug was administered. Of 600 cases in which delay in the birth of the infant occurred, in nine mothers morphine had been administered within four hours of birth, and no difference was noted between the infants in these cases and those of delay due to unknown causes. Resuscitation was effected by means of carbon dioxide and oxygen. Nitrous oxide gas and oxygen gave the best results in the second stage of labor and during delivery. The duration, strength and frequency of the contractions increased in more than 50 per cent of the cases. There were no cases of postpartum hemorrhage due to the administration of anesthetic drugs.

 *Hypercalcemic Ankylosing Arthritis and Parathyroidectomy M. P. Weil —p 211
 *Sodium Thiosulphate for Unexpected Symptoms of Gold Therapy J. Vignati, U. Hradiste and V. Skolnik —p 212

Hypercalcemic Arthritis and Parathyroidectomy—Weil does not feel that either the character of an ankylosing arthritis or a hypercalcemia offer sufficient evidence on which to base parathyroidectomy. Therefore fourteen patients were chosen who were afflicted with generalized chronic arthritis and had resisted all other treatments. In all these patients, partial thyroidectomy was performed as well as parathyroidectomy when the parathyroids could be found. In three patients with rhizomelic spondylitis, amelioration occurred in two (in one of whom the parathyroids were found to be abnormal). In two patients with multiple arthritis and goiter, considerable improvement occurred in one in whom partial thyroidectomy was performed but the parathyroids were not found. The other showed improvement for about six months. Of the nine remaining patients with multiple arthritis who were operated on, one died and one did not have the operation completed. In four cases no change occurred; in one there was considerable improvement and in one in which the parathyroids were not found there was also a marked amelioration of the condition. The author believes that although improvement from the operation is possible in some instances poor results occur and that the interpretation is disputable and the indications are lacking in precision.

Sodium Thiosulphate for Unexpected Symptoms of Gold Therapy—Vignati and his associates describe their method of gold therapy with which they have never had serious accidents. The agents employed in their gold preparation were gold chloride, anhydrous sodium sulphite crystallized sodium thiosulphate and distilled water each chemically pure. To obtain a solution containing 0.01 Gm of gold per cubic centimeter of solution for injection, they prepared a solution of 2 Gm of sodium sulphite, and 65 Gm of sodium thiosulphate in 40 cc of distilled water. To this they added drop by drop and with shaking, a solution of 1 Gm of gold chloride dissolved in 25 cc of distilled water. Finally the solution was filtered, neutralized with sodium hydroxide and sterilized for one hour at from 90 to 100 C. A total of 217 patients with pulmonary tuberculosis and some additional patients with rheumatism, syphilis, asthma and atrophy of the optic nerve received treatment with this preparation. No serious reactions resulted and in four cases was there a short, afebrile exanthematous reaction after which treatment was resumed without incident. The authors believe that the apparent protective action of sodium thiosulphate against reactions to gold therapy needs to be verified on a large scale by other investigators.

 *Latent Icterus of Chronic Cholecystitis E. Chabrol and A. Busson —p 228
 *Cobalt as Vasodilator J. M. le Goff —p 231

Latent Icterus of Chronic Cholecystitis—In studying forty-five cases, Chabrol and Busson found that pigment cholemia, through its constant presence is more valuable than cholesterolemia in recognizing chronic cholecystitis without icterus. Chauffard once remarked that hypercholesterolemia is incompatible with diseases of the biliary tract. Consequently it is precisely the hepatobiliary disease that seems to condition the amount of bilirubin in the blood in chronic cholecystitis. Undoubtedly the familial tendency may be a factor. This explanation may be valuable for a certain number of diseases but it is generally surprising to see the pigments return forty-eight hours after surgical intervention for removal of the inflammatory focus. The authors believe that before passing judgment on the precise mechanism which governs this latent pigment retention (hepatitis, angiocholitis, cholelithiasis, spasm or pancreatic involvement) it is important to know the rate of increase in order that surgical indications may benefit. Out-

side of icterus, hypercholesterolemia is more a symptom of atherosclerosis or of chronic nephritis than a manifestation of biliary lithiasis. The authors state that the bilirubin content of the blood is not higher in cases in which the calculi are obvious to the roentgen rays. In a great number of cholemic states the hyperbilirubinemia disappears the day following surgical intervention. In twelve cases of gastroduodenal ulcer the bilirubin content of the blood was normal eleven times. The one exception (20 mg per thousand cubic centimeters) concerns a case presenting subhepatic adhesions forming a perivisceral veil and marked periduodenitis. Familial cholemia may be present when there is a contrast between the high rate of the bilirubinemia and the absence of pain provoked by Murphy's sign. When a cholic inflammation is complicated by a vesicular reaction, variance is generally found between the weak bilirubinemia and the abnormal degree of subhepatic sensitiveness. The authors recognize that the pigment content of the blood easily tends to individualize the group of chronic colitis without hepatovesicular involvement, the rate of bilirubin is then normal. Forty-eight hours after operation there was scarcely any increase in the bilirubin in cases in which the liver was unaltered; this was observed in various operative conditions, such as appendicitis, hernia, hysterectomy and ovariectomy. The authors found that early attacks of bilirubinemia in patients operated on for cholecystectomy without drainage are not incompatible with a progressive amelioration of the condition of these patients. In the majority of cases of cholecystitis the pigment cholemia reaches its normal rate in two or three weeks, the maximum being three months after operation.

Cobalt as Vasodilator—Le Goff experimented with cobalt compounds on rabbits and dogs. The cobalt was administered either by mouth or by subcutaneous injections in an isotonic solution. On the basis of experiments in animals, the author decided to test the action of cobalt compounds in human beings. In three cases the cobalt was administered by mouth and in seventy-two by intramuscular injections of an isotonic solution of cobalt chloride, citrate and salicylate. In conclusion the author states that a few centigrams of cobalt compounds from 0.01 to 0.05 Gm are not toxic for man. Their main effect is the vasodilatation of the blood vessels of the face and ears with a fall in blood pressure. This redness of the face seems to be produced by a paralyzing effect of cobalt acting on the sympathetic system.

 Chloropicnic Hyperazotemia A. Creazzo —p 162

Weltmann's Serum Reaction in Hepatopathy—Massobrio and de Michelis experimented with Weltmann's serum reaction on hepatic diseases, diseases of the biliary tract and hemolytic icterus. To an equal amount of serum (0.1 cc) they add 5 cc of a solution of calcium chloride in distilled water diluted in arithmetical progression from 0.1 per hundred to 0.1 per thousand and boil the whole batch on a water bath for fifteen minutes, during which time the tubes must be shaken continually. The authors found that Weltmann's serum coagulation reaction cannot give early indication of a hypofunction of the liver but is valuable for differential diagnosis of hepatic diseases. In advanced cirrhosis the reaction showed a marked and constant increase of the coagulation column. Inflammatory processes of the biliary tract and tumors of the liver and of the biliary system showed either shortening of the coagulation column or normal values. In view of the results of the reaction the authors take into consideration the possibility of a concomitance of processes influencing the coagulability of the serum in an opposite or in the same way. In regard to the relation of the column of coagulation to the alterations of the hematic protein picture in hepatic diseases they state that there exists a certain parallelism between increase of the column

of coagulation and inversion of the protein quotient, particularly in forms with pronounced cellular involvement. The fact that diseases with marked inversion of the protein quotient sometimes present a shortening of the column of coagulation indicates that the two conditions are strictly dependent on each other.

Weltmann's Serum Reaction in Some Diseases—Pellegrini and Barsini studied the effect of the Weltmann reaction on the serum of 300 patients presenting various diseases, 28 with exudates and 16 with transudates, 12 with normal and 4 with pathologic cerebrospinal fluids. The authors found that the modifications undergone by serum coagulation constantly reflect the nature of the lesion developing in the organism and vary according to whether the pathologic process is exudative or sclerotic. In inflammatory diseases of the biliary tract there is an alteration of the coagulation toward the higher electrolytic concentrations, while the opposite behavior is evinced by the cirrhotic lesions of the liver. Since cirrhosis also embraces catarrhal icterus, it corroborates the prevalently hepatic nature of this disease. In other diseases in which the hepatic function may be involved, as in pernicious anemia, diabetes mellitus and chronic alcoholism, the effect of the reaction is analogous to that observed in cirrhosis. This behavior was observed without exception in twenty-one cases of postencephalitic parkinsonism. The authors maintain that the reaction of Weltmann is one of the more sensitive indexes of altered hepatic function.

 Treatment of Pollen Allergy K. Hansen—p. 210
 Most Important Infectious Diseases C. Hegler—p. 213
 Nutrition of Healthy and Sick Charity Recipients H. Bartelmaier—p. 218

Atypical Pneumonias During Childhood—Watjen reports the histories of four cases of atypical pneumonia in children, which ended fatally. The postmortem examinations revealed that the atypical pneumonic changes were characterized by more or less extensive hemorrhagic infiltration of the pulmonary tissues, involvement of the interstitial tissues of the lung, and, with the exception of the first case by pulmonary abscesses. The discovery of the pulmonary abscesses during the necropsy was a surprise in that their existence had not been indicated by the clinical aspects. The anatomic and bacteriologic aspects of the reported cases resembled those of influenzal pneumonia. All four cases developed outside of an influenza epidemic, and it could not be decided whether they were precursors or the late stragglers of an influenza epidemic. The detection of influenza bacilli in three of the patients is noteworthy, because it again raises the question of the causal role of Pfeiffer's bacillus in influenza and in influenzal pneumonia. The author thinks it possible that the Pfeiffer bacillus plays a part in influenzal pneumonia and calls attention to the possibility of an infection by carriers of the bacillus outside of an influenza epidemic. He thinks that these atypical cases of pneumonia, which resembled influenzal pneumonia, were the result of the same factors that in the course of an influenza epidemic occur with greater frequency. He assumes that the peculiarities of the pathogenic organism and a reduced resistance in the patient are the dominating factors in these atypical pneumonias.

Calcium Therapy of Pneumonia—In enumerating the beneficial effects of calcium therapy, Zapel mentions the stimulating influence on the sympathetic nervous system, the anti-inflammatory action, the favorable effect on the blood coagulation, the reduction of the irritability of the cerebral cortex, the significance of the calcium ions for the osmotic pressure, the digitalis-like action on the heart and the favorable effect on the excretory system. Since a 20 per cent solution of calcium gluconate gave promise that it would combine the favorable effects of hypertonic solutions on the circulation with the effects of calcium preparations, the author decided to employ a 20 per cent solution of calcium gluconate in influenzal and pneumonic pulmonary complications. The dosages varied

according to the severity of the disorder. From 10 to 50 cc was divided in several daily doses. Some of the injections were given intravenously and some intramuscularly. As a rule the treatment was continued until the fever had completely disappeared. The author admits that it is difficult to estimate the results of the treatment in an objective manner, but, on the basis of observations in 200 cases of influenza, influenzal bronchitis and pneumonia he stresses that the preparation is well tolerated in both the intravenous and the intramuscular injections. It exerts a digitalis-like action on the heart and on the peripheral circulation. In influenzal bronchitis and in pleurisy an antexudative and an anti-inflammatory effect can be observed. The superiority of the 20 per cent solution over the formerly employed 10 per cent solution lies in the fact that it acts more rapidly and that larger amounts of calcium can be administered with the same quantity of fluid. About the effects on the calcium content of the blood, the author states that his observation corroborated those reported in the literature.

Significance of Muscular Tonus for Blood Circulation—Mateeff and Petroff point out that gravitational disturbances in the circulation are due to the fact that, under the influence of the hemostatic pressure, the capillaries and the small and large veins of the lower portion of the vascular system become dilated and take up a larger amount of blood than is the case when the patient is reclining. The hemostatic pressure exerted on the inside of the vascular walls is counteracted by their elasticity and by the counterpressure of the surrounding tissues. The elastic resistance of the vascular walls is not constant but variable, depending on the tonus and the influence of the innervation. The authors think that the circulatory significance of this vascular tonus should not be overestimated and that the hemostatic pressure is counteracted mainly by the pressure from the surrounding tissues, especially from the muscular tonus. If the latter factor really has this predominating significance for the circulation, it is to be expected that persons with a pathologically decreased muscular tonus are subject to circulatory disturbances when they are standing up. The authors investigated this problem on persons with reduced, increased and normal muscular tonus by determining the pulse rate and blood pressure when the persons were reclining and standing. They found that in patients with pathologically decreased muscular tonus the hemostatic pressure during erect posture produces a disturbance in the blood distribution which is so severe that in a comparatively short time (from five to twenty-five minutes) the circulation fails completely and the so called gravitation shock develops. Bandaging of the lower extremities up to the pelvis by means of an elastic bandage counteracts the gravitational disturbances in the blood distribution of these patients. In patients with pathologically increased muscular tonus and in healthy persons with good muscular tonus, the gravitational disturbances in the blood distribution are extremely slight. The normal muscular tonus prevents the abnormal dilatation of the capillaries and of the small and large veins of the lower parts of the body and facilitates the backflow of the blood to the right side of the heart.

Mechanism of Takata-Ara Test—Schindel states that the Takata-Ara reaction which was first suggested for the differen-

tiation of the changes in the cerebrospinal fluid in neurosyphilis from those in bacterial meningitides, was later employed on the serums of patients with hepatic diseases. Jezler's results seemed to indicate a globulin increase in liver disease, but Skouge, who also investigated this problem, proved that a considerable increase in globulin does not necessarily lead to a positive outcome of the Takata-Ara test. The contradictory results of Jezler and Skouge induced the author to study the mechanism of the Takata-Ara reaction. He found that by the addition of the lower fatty acids, such as formic, acetic, propionic and butyric acids, to the dilution series of a serum it is possible to obtain a positive reaction in a serum that otherwise gave a negative Takata-Ara reaction. The addition of mineral acids, however, did not have this effect. The flocculation following the addition of the low fatty acid takes place exactly as in the naturally positive Takata-Ara serum, in the dilution of 1:32. By adding one of the lower fatty acids to the serum as such, it was possible to produce a type of flocculation which resembles that in ascites. Transformation of the experimentally as well as the naturally positive Takata-Ara reactions into negative ones could be effected by the addition of a solution of sodium or potassium hydroxide. These observations indicate that it must be questioned whether a positive Takata-Ara reaction is the result of changes in the composition of the serum proteins, for it is not likely that in the case of the addition of the fatty acids the process is simply a protein precipitation. Further experiments are being conducted to determine to what extent the fatty acids that develop in the intermediate metabolism play a part in the outcome of the reaction.

Chronic Intestinal Disturbances—Wendt relates the history of a woman, aged 39, presenting symptoms similar to those observed in celiac disease of children. Severe enteritic disturbances existed, particularly in the small intestine. Roentgenoscopy without a contrast medium indicated the presence of large amounts of fluid in the small and large intestine for there were numerous shadows with level surfaces. Clinical examination revealed a fluctuating abdomen and splashing sounds could be elicited. Following ingestion of the barium meal, there was a comparatively normal evacuation of the stomach, but the filling of the small intestine was irregular. In some portions of the small intestine the passage seemed to be accelerated and in others retarded. Examination of the duodenum revealed *Bacillus coli*. In spite of the fact that the pancreatic and biliary secretions were normal, there existed severe disturbances in the resorption of fats, proteins and carbohydrates. The patient had tetanic attacks and examination revealed hypocalcemia, hypophosphatemia, extensive osteoporotic processes and spontaneous fractures. Acidosis existed and a disturbance in the carbohydrate metabolism was indicated by the low blood sugar curve following a dextrose tolerance test. The examination of the blood picture revealed hypochromic anemia and leukopenia. The author concludes that this is a true case of celiac disease.

Percutaneous Application of Histamine—It is pointed out by von Issekutz that in the use of skin irritants it is always

histamine or a substance that acts similarly that produces the hyperemia. This knowledge led to the direct application of histamine. Application by iontophoresis, in which a histamine-containing filter paper is covered on one side with aluminum and serves as an anode, is perhaps the best method. The filter paper is moistened and applied to the skin and, shortly after a current of from 3 to 15 milliamperes has been passed through the anode, the histamine action is evident. However, since this method requires a special apparatus and a certain experience, it is not always practical, and the author devised a method that can be applied without an apparatus. He shows that the penetration of histamine is prevented mainly by the fat-covered horny layer of the skin. Because of this layer the histamine ointment can enter the skin only through the hair follicles, and, in order to facilitate the penetration, the horny layer has to be loosened. The author effected this by passing a fine glass paper over the skin. The pressure should be slight, because pain, detachment of the deeper layers of the epithelium, exposure of the corium and appearance of petechial hemorrhages must be avoided. The rubbing is continued for from twenty to thirty seconds, so that the upper epithelial layer is loosened and the exfoliated particles cover the skin like a fine meal. This loosening of the epithelium and the intracellular microscopic fissures are sufficient to facilitate resorption of the histamine. A further improvement can be effected by using a water-soluble gelatinous base rather than a fatty base. The author found also that if his method of preparing the skin is employed the histamine preparation does not need to be so concentrated. He found a 0.5 per cent gelatinous histamine preparation more effective than a 2 per cent fatty histamine ointment.

Glycosuria and Hyperglycemia in Diseases of Coronary Arteries—Among 118 patients with coronary sclerosis or with coronary thrombosis, in whom Edelmann studied the carbohydrate metabolism, there were 62 with temporary or continuous glycosuria or hyperglycemia. The majority of these patients had a latent diabetes mellitus. It was found also that coronary sclerosis frequently concurs with arteriosclerotic occlusion of the dorsal artery of the foot, and in both conditions there frequently exists a diabetic disturbance of the metabolism. The author concludes that latent diabetes is one of the most important etiologic factors in the development of arteriosclerosis. He demands dietary measures in coronary sclerosis and in sclerosis of the arteries of the foot and he thinks that eventually dietary restrictions could be instituted for prophylactic purposes. He calls attention to the possibility of treating coronary sclerosis and sclerosis of the arteries of the foot by radium irradiation of the region of the heart and by the simultaneous administration of insulin.

Histidine in Urine of Pregnant Women—Kapeller-Adler who investigated the occurrence of histidine in the urine of pregnant women, succeeded in finding a specific method for the detection of histidine. A reexamination of Voges' test convinced her that it is not reliable. In her method of determining the histidine in the urine the phosphates are eliminated first then the histidine is concentrated and after suitable treatment, colorimetric examination is done. The following reagents are required for the colorimetric test: (1) a 1 per cent solution of bromine in 33 per cent solution of acetic acid; (2) two parts of ammonia mixed with one part of a 10 per cent solution of ammonium carbonate; (3) a 1:1000 standard histidine solution; (4) a tenth normal solution of potassium permanganate. After giving a detailed description of the procedure the author

presents tabular reports of the outcome of the tests. The urines from pregnant women always gave a positive reaction, but the quantities of histidine fluctuated and there was no relation between the quantity of histidine and the stage of advancement of the pregnancy. In the urines of sixty-two pregnant women, the values fluctuated between 6 and 74 mg per hundred cubic centimeters. It was not possible to determine at what period of pregnancy the histidine elimination begins, but positive reactions were obtained during the sixth week, and in some instances only traces of histidine were demonstrable during the fifth and sixth week, while a week later histidine was detectable in noticeable quantities. Tests on seventeen healthy nonpregnant women resulted in negative reactions in all but one of the cases, and of the urines of ten nonpregnant women with various disorders two gave positive results: one was from a woman with bronchial carcinoma and the other from a woman with exophthalmic goiter. The urines of six women with amenorrhea and of one with myoma were entirely free from histidine. Examination of the urines of puerperal women indicated a slow decrease in the histidine values. In ten out of eleven urine specimens the histidine and the Aschheim-Zondek tests gave identical results, but in one case of negative Aschheim-Zondek reaction a large amount of histidine was discovered. Somewhat surprising was the observation that the urines from healthy men gave positive histidine reactions much more frequently than did those from healthy women. The author is now conducting experiments to determine whether the histidine elimination can be modified by hormones. She also describes a rapid control reaction for the demonstration of histidine in the urine.

*Functional Disturbance of Thyroid in Industrial Chronic Mercurial Poisoning M. A. Kazakevich —p 1247

Functional Disturbance of Thyroid in Mercurial Poisoning—Kazakevich investigated 133 workers in a mercury plant. Of these, 48 were men and 85 women. 60.9 per cent of the group were between 20 and 30 years of age. The duration of occupation was from six months to three years. Manifestations of a thyrogenous character with an enlargement of the thyroid were observed in 57.3 per cent. The incidence of vasomotor neurotic states of thyrogenous character raises the percentage to 88.9. The following constituted characteristic complaints: irritability, somnolence, poor memory, disturbed sleep, headache, tremor of the extremities, particularly of the fingers, flushes, sweating, palpitations, falling out of hair, increased salivation, bleeding gums, weakness and apathy. Among the characteristic objective signs were tremor of the eyelids, dilated pupils, exophthalmos, absent or weakened pharyngeal and conjunctival reflexes, tremor of the fingers, red dermographism, increased sweating and salivation enlarged and tender thyroid, and falling out of hair. Double color line of the gums, pale skin and mucous membranes, arterial hypotonus and labile pulse were rather frequent signs in chronic mercurial poisoning. Enlargement of the cervical and inguinal lymph nodes was present in almost all cases. In the beginning the nervous system reacts to mercurial intoxication with a vasomotor neurosis, which gradually develops into hyperthyroidism if the intoxication continues. The highest values of mercury excreted in the urine were found in adolescents up to the age of 20 and disturbances of the thyroid function and of the vegetative nervous system occurred in them with greatest frequency. The incidence of hyperthyroidism was higher in women than in men. The author urges a number of preventive measures for the removal of mercurial vapors, exclusion of workers below the age of 20, and the consideration of limiting in some cases the period of employment to six months at one time. Administration of salts of iodine and of bromine because of the readiness with which these halogens combine with mercury is recommended just as soon as the first signs of mercurial irritation appear.

Cerebral Symptoms in Course of Operations on Pleura—Petren reports three cases of severe cerebral complications occurring during a surgical intervention on the pleura or the lung. In one case a thoracotomy was performed for the cure of pleural empyema, in the second case the cerebral symptoms developed after two punctures of the exposed lung, and in the third they appeared in the course of a plastic procedure on the thoracic wall for the closure of a persisting empyema cavity. Sudden loss of consciousness was the mode of onset in all three cases, the rest of the symptoms exhibiting considerable variation. In the first case there developed a hemiplegia, facial paresis, almost complete aphasia and later clonic convulsions and death twenty hours after the onset. In the second case there developed hemiplegia, facial paresis, aphasia and amaurosis while amaurosis was the only focal symptom in the third. Necropsy in the first case revealed nothing abnormal in the brain tissue. Hemiplegia, aphasia and the visual disturbance in the second case disappeared in a few hours while in the third case the amaurosis disappeared in the course of three days. The earlier views considered this phenomenon in the nature of a nervous reflex, hence such terms as pleural reflex, pleural shock, pleural epilepsy and pleural eclampsia. Wever injected air into the carotid artery and produced the same cerebral symptoms as in the cases under consideration. Ophthalmoscopic examination of these animals revealed air embolism of the retinal vessels. Postmortem observations were as a rule negative. Wever found air in cerebral arteries in two cases of sudden death. The author concludes that the theory of pleural reflex has been replaced by the concept of air embolism of the cerebral vessels, the retinal vessels and later the coronary vessels, as the cause of the cerebral complications in operations on pleura and lung.

Disinvasion of Intestine with Aid of Fluorocopy—Sjostrom states that for the last three years all cases of intussusception admitted to the Lund Hospital were referred to the roentgen department. In addition to the establishment of the diagnosis an attempt was made in almost all cases to disinvaginate the intussuscepted intestine under fluoroscopic control with the aid of a barium enema under pressure employing massage and taxis. The successful cases were kept under observation, the failures were submitted immediately to a laparotomy. Disinvasion was successfully carried out by this method in twenty-two of thirty-eight cases, the children being discharged as cured. In the remaining sixteen, operation was performed immediately after the attempt at reduction under roentgen control had failed. In all of these, reduction was accomplished at the operation. It is the ileocecal intussusception that can be reduced by a barium enema and taxis under fluoroscopic control. In nineteen cases of this type, failure was encountered only once. The nonileocecal intussusceptions can frequently be diagnosed roentgenologically, and operation should be performed at once. Cases in which the history is shorter than twenty-four hours are most favorable. Taxis should not be attempted in cases in which there is a history of more than two days. The author does not recommend non-operative disinvasion as an independent method. In his experience it proved valuable as a preoperative means of eliminating about two thirds of all the cases in which a cure may be brought about by conservative means, while in the remaining one third the operation may be carried out without an increase in mortality.

FOR THE UNITED STATES PUBLIC HEALTH SERVICE

This presentation of a uniform type of procedure in the treatment of early syphilis is the product of a genuinely massive investigation of world-wide scope, sponsored by the League of Nations Health Organization and carried through in the United States by the combined efforts of the United States Public Health Service and a group of five university clinics aided by the generosity of several donors. The material embraces the records of 75,000 cases of syphilis, of which 3,244 were examples of early syphilis followed for six months or more and 383 followed for as long a period as five years or more.¹ These figures while not in themselves impressive, express an aggregate material larger than any as yet fully evaluated in the literature and are entirely capable of serving as a basis for a definition of the aims and methods of modern effective treatment for early syphilis. The time covered ranges from 1916 to 1931 for the collection of the cases, and twenty months for the study of the records, so that the period embraces essentially that of modern syphilologic practice and its conclusions may be accepted as applicable to the work of today.

ELICIBILITY OF EARLY SYPHILIS FOR STANDARDIZED PROCEDURE

The strength of treatment in late syphilis lies in individualization but attention to the individual is not nearly so essential a factor in the management of early syphilis. While no one can deny that individualization has its place throughout the management of early syphilis in contrast with late has proved beyond question to be amenable to a considerable degree of routine standardization and mass technique the principles

of which have so wide a degree of applicability that they can be formulated into definite rules and systems for all but universal use. The clear definition of the aims possible at the early stage of the disease, the youth and relatively good health of the patients, their freedom from the intrinsic damage in later life produced by years of syphilitic infection, all make standardization easy and acceptable and, in fact, a positive asset in the great aim of the ultimate extinction of the disease.

THE AIMS TO BE ACHIEVED

Again in contrast with late syphilis, the aim in the period of latency and late manifestations is preventive and symptomatically curative rather than radically curative. The period of infectiousness and transmission over (except in the pregnant woman), "cure" in the sterilizing or complete sense is probably out of the question. In early syphilis, on the other hand, the evidence of the laboratory and the more slowly accumulated presumptions of clinical experience indicate that radical or complete "cure" is possible by an appropriate treatment technique, and infectiousness, limited largely to the primary, secondary and relapse manifestations of the first two years and to the semen, becomes the crucial issue in public health control. The aims in early syphilis may therefore be crisply defined as, first, the prevention of transmission by treatment and, second, the individual "cure." This order of arrangement has a proper social significance, and the aims are accomplishable to a degree presently to be defined.

PRINCIPLES GOVERNING THE CONTROL OF INFECTIOUSNESS

Present knowledge of the biology of the disease, and the conclusions drawn from the study of cutaneous and mucosal relapse by the University of Pennsylvania group² and the presentation of this problem from the Cooperative Group material³ have been summarized in the following condensed statement of the principles governing the control of infectiousness in early syphilis. Any standardization of treatment must, it is believed conform to these principles and take account of these conclusions to be acceptable.

CONTROL OF INFECTIOUSNESS IN SYPHILIS⁴

1 Infectiousness in syphilis is a function of three factors (a) time (b) arsphenamine (c) individual predisposition to relapse.

2 Infectiousness is not a function of the serologic state of the patient. No serologic test has any value as a proof of infectiousness or noninfectiousness early or late.

2 Stokes J H, Besancon J H and Schoch A G. Infectious Recurrence and Mucocutaneous Relapse in Syphilis. J A M A 96:344 (Jan 31) 1931.

3 Stokes J H, Cole H N, Moore J E, O'Leary P A, Parran Thomas and Wile U J. Venereal Disease Information 12:55 1931 (read before the International Congress of Dermatology and Syphilology, Copenhagen Aug 5-9 1930).

4 From Stokes J H. Modern Clinical Syphilology, ed 2. Philadelphia W B Saunders Company 1934 (to be published) figure 99 p 213.

The syphilis clinics of the University of Pennsylvania, Western Reserve University, the Johns Hopkins University, the Mayo Clinic and the University of Michigan assisted by the U S Public Health Service and supported by a special fund contributed by an anonymous donor and a grant by the Milbank Memorial Fund.

1 Venereal Disease Information 13:135-165 20-23 1931.

3 Syphilis, treated or untreated, is most infectious early, grows less so with lapse of time, is rarely infectious (but may be so) after five years. Late syphilids and late prenatal ("congenital") cases are not infectious.

4 Therefore, spur for time and delay in any issue involving infectiousness (i. e., marriage, intercourse).

5 Infectiousness is controlled and syphilis will be extinguished, if ever, as a health problem, by treatment of the infectious person.

6 The public health responsibility of the physician is therefore with the early months and years of the disease.

7 Treatment to control infectiousness must be with the arsphenamines. No other drug will do.

8 The use of arsphenamines must not be delayed even to secure any minor individual immunizing advantage.

9 Treatment to control infectiousness must be continuous, not intermittent, and last at least eighteen months. Rest periods encourage relapse.

10 Acetarsone (Stovarsol), tryparsamide, and nonspecific (including fever) therapy must not be expected to control infectiousness.

11 Search for infectious lesions is ineffective, except as an adjunct. Hence inspection of prostitutes is useless.

12 Instruction to and cooperation by the patient is ineffective and untrustworthy except as adjunct.

13 The amount of arsphenamine required is not less than twenty injections. The critical point is between 5 and 9.

14 Heavy metal is required as an adjunct.

15 The infectiousness of semen and vaginal secretions even in the absence of lesions, in early and latent syphilis demands absolute mechanical protection in intercourse treatment or no treatment. Continence, advised, is seldom practiced.

16 Inspection, instruction, control and protection are more essential in rest periods than under treatment.

17 There is a relapsing type of early syphilis regarding which no rules or predictions can be formulated.

18 In relapsing types, infectiousness may reappear immediately after, or even during (arsphenamine resistant), treatment with the arsphenamines.

19 Alcohol, dirt, bad hygiene, irritants including tobacco, sweat, friction (intercourse) predispose to infectious lesions.

20 The great promoter and source of relapse is the short arsphenamine course (one to four injections) unsupported by other treatment.

21 Treatment prophylaxis (after exposure) is unreliable. If given it must be followed through.

22 Adequate examination of patients would protect physicians, dentists, nurses and transfusion recipients from most risks of accidental infection.

23 The nonpregnant, nonsyphilitic woman should be protected mechanically and by treatment of the partner.

24 Conception should not take place except under treatment control.

25 The child of the pregnant syphilitic woman should not be destroyed, but protected *in utero* by treatment of the mother, before and after conception, and of the father, if syphilitic, before conception.

THE INDIVIDUAL "CURE"

The term "cure" must be used with circumspection and the use of quotation marks expresses its status as a clinical presumption rather than as an established fact. There are no available criteria of "cure" at this time, and many more years of observation will be required to establish its status. None the less, for practical purposes "cure" is a complete extinction of all symptoms and signs of the disease, with nontransmission of the infection over a lifetime, or as close an approximation to it as present follow-up clinical material permits one to study. "Cure" as here used is therefore essentially what is spoken of as "satisfactory result" in the Cooperative Clinical material that the patient has been followed for two years or more and that during one

probationary year he has had no symptoms of syphilis, examination of his blood has been consistently negative, and he has had a negative spinal fluid examination and a negative physical examination or has had a reinfection.

Briefly expressed, among patients under observation and treatment for two years or more, the highest proportion of satisfactory results obtained under conditions stated in the next paragraph was 71.4 per cent under all methods of treatment taken in the aggregate and 86.4 per cent satisfactory results when treatment was "continuous" as distinguished from "intermittent," "intensive" and "irregular."

THE "GOLDEN OPPORTUNITY" REDUCED TO FIGURES

The term applied by Pusey to the superior outlook of treatment begun in the primary stage of syphilis before the blood serologic tests become positive ("seronegative primary") has been justified abundantly by statistical analysis. The proportion of "cures" when treatment is begun in the seronegative primary stage (diagnosis by dark field or other identification of *Spirochaeta pallida*) is, as given, 71.4 per cent average and from 83 to 86 per cent best results. When, through failure of the patient to present himself or of his physician to diagnose primary syphilis until the blood test becomes positive, treatment is not begun until the so-called seropositive primary stage "cure" is attained in only 53.3 per cent by average and from 64 to 70 per cent by the best methods. This represents a clear loss of 18 per cent in outlook for "cure" by the delay. If the patient goes on to the development of a secondary eruption, of course with a positive blood test, "cure" is attained in only 50 per cent by average and 61 to 82 per cent by best methods. This represents a possible loss of 21 per cent by average and 14 per cent by best methods over the outlook prevailing when treatment is begun in the seronegative primary stage.

The figures for other elements in the clinical picture of early syphilis when the patients were under treatment or observation for six months or longer are as follows. Fixed positive blood tests develop in 3.8 per cent when treatment begins in the seronegative primary stage, in 14.5 per cent in the seropositive primary stage, and in 13.3 per cent in the early secondary stage. Fixed positiveness in early syphilis is a serious matter, for in this condition 30.6 per cent proved to have neurosyphilis, while among those rendered Wassermann negative only 18 per cent had neurosyphilis. All other forms of relapse and progression are from two to five times as frequent among those who are not rendered Wassermann negative as in those who are. Serologic relapse occurs in 12 per cent of the seronegative primary group, in 16 per cent of the seropositive primary group and in 15 per cent of the early secondary group. Owing in part to the chronology of the disease and in part to a possible protective or inhibitive effect of cutaneous and mucosal secondaries on mucocutaneous relapse, in this one aspect of early syphilis and in this only does one observe any apparent advantage gained by the patient whose treatment is deferred. 16 per cent seronegative primary, 20 per cent seropositive primary, and 9.5 per cent relapse when the patient has developed his secondary eruption.

It is apparent, therefore, that his duty to the individual patient, dear to the heart of the conscientious physician, even more than his duty to the public health, demands the earliest possible diagnosis, as well as the earliest possible application of treatment.

COMBINED ARSENICAL AND HEAVY METAL
TREATMENT AND ITS FUNCTIONS

The investigations of the Cooperative Clinical Group were not designed to deal with the question as to whether arsphenamine or heavy metals should be used alone in the treatment of early syphilis, nor is there opportunity here to review the literature on this question. It is accepted now as axiomatic that no patient with early syphilis should be treated by the sole use of an arsenical. To do so may lead to an unprotected state of high susceptibility to the most critical forms of relapse involving the nervous system (neurorecurrence), the liver and other structures. In an unknown proportion of cases it does more—it directly predisposes the patient to an allergic reaction that forms the basis of so-called malignant precocious tertiarism—the development of highly destructive gummatous lesions within a few months of the primary stage. The protection of the patient from these dangers consists in the invariable use of mercury or bismuth compounds in conjunction with arsenical therapy, either simultaneously (concurrently) or in alternating courses. While there is some dispute in the literature as to the relative merits of the concurrent and the alternating use of the two modes of treatment, the material here presented embraces both types and no effort is made to differentiate between them. Just as no patient should be treated exclusively with an arsenical, so also no patient should be treated exclusively with a heavy metal—even with bismuth, for all that it possesses greater spirocheticidal qualities than mercury. Its inferiority to the arsphenamines in this regard has been clearly demonstrated and the necessity for the use of an arsphenamine for the control of infectiousness is borne out by the present investigations.

THE CONTROL OF RELAPSE BY TREATMENT

The general principles of this phase of treatment from the standpoint of infectiousness have been summarized, but it is worth while to emphasize further the existence of the relapsing type of patient, whose recurring infectiousness is a menace to the public health (12 per cent of the 3244 patients), and to point out that the occurrence of weak positive serologic tests among the negatives in an otherwise favorably progressing patient is a serious matter. Of the 113 patients in whom this occurred, 18 per cent subsequently developed a clinical or serologic relapse. The figures supporting the statement that arsphenamine is absolutely necessary to the control of infectious relapse in the treatment of early syphilis are clearly defined, 35 per cent of infectious relapsing patients had had less than five injections of arsphenamine and 81 per cent had had less than fifteen injections. Of those who had twenty or more injections only 13 per cent ever sustained an infectious relapse. Thus twenty injections of an arsphenamine becomes the optimal number needed in the individual case to control the danger he represents to his contacts and to the public health.

It should be emphasized that in the first six months after treatment ceased, nearly one half (45 per cent) of the relapses had occurred. By the end of the first year, 73.6 per cent, by the end of the second year, 91 per cent. Hence the critical time of probation for the treated patient is the two years following the cessation of treatment, and no promises should be made, no precautions relaxed and no observation neglected during this period. An increased rather than a diminished frequency of blood tests, and periodic inspection of

the mucosae, skin and anogenital region are essential during this probationary period. Especially should pregnancy and mechanically unprotected intercourse be even more strictly controlled after than during standard treatment in early syphilis.

THE DANGER OF THE REST INTERVAL OR LAPSE

One of the most important contributions of recent years to the technic of treatment of early syphilis has been to the question of intermittence as distinguished from continuity of treatment. Those who recall the nineteenth century syphilology will remember the practical necessity of rest periods from treatment, enforced by the high toxicity and debilitating effects of the one effective antisypilitic drug, mercury. With the advent of rapidly eliminated tonic agents such as the arsenicals, which leave no trail of anemia and weight loss in their wake, and of highly effective and sometimes markedly stored but relatively nontoxic agents such as bismuth, much that appears as intermittent is really continuous treatment. While other investigations, including especially the foremost American study by Moore and Kemp, have supported the view that even the most modern treatment should be continuous and not intermittent, the Cooperative Clinic Group investigation seems to set the capstone to the demonstration. It may now be said with positiveness that the old practice of administering treatment in early syphilis by fits and starts, conditioned on the Wassermann report of the blood, is pernicious, that even the introduction of a few weeks of complete rest from treatment into the management of the first eighteen months of the disease is likely to be profoundly injurious, that the patient who lapses or escapes treatment during this period is his own worst enemy, and that no rest intervals, and a regimen in which the patient is constantly receiving either an arsenical or a heavy metal during the first year of the disease or longer, if the indications require, is the best and safest modern practice, in the interest both of the patient and of the public health.

The figures supporting these rather forcible and uncompromising statements are clear cut. They were obtained both by a study of infectious relapse and by the analysis of serologic and clinical results on the basis of four modes of treatment: the continuous, just described, the intermittent, in which rest intervals or complete breaks in treatment were introduced into the normal course, either purposefully or through the patient's negligence, the intensive, a system that has had some popularity in this country, and involves a short (three or four injection) course of arsphenamine alternating with a heavy metal course in units with long rest intervals between the arsenic-heavy metal units, and, finally irregular treatment, totally irregular and uncontrolled, with long and short courses, rest intervals and so on in fortuitous disarrangement.

Continuous treatment, then, whether prolonged or brief, and practically regardless of the drugs used, is superior in its results to the intermittent or other schemes of treatment. The continuous method secured the reversal of the blood Wassermann reaction by the end of a year in 81.8 per cent, whereas the intermittent scheme of treatment with rest intervals of a month or more secured only 37.3 per cent of reversals, and irregular treatment gave only 4.7 per cent of Wassermann reversals within a year. It appears, then, that that great bugbear of physician and patient, the fixed or irreversible positive Wassermann reaction in treated early syphilis, lies at the door of the rest interval or

lapse from treatment rather than in any peculiarity of disease or drugs

In the matter of relapse, treatment continuously administered resulted in fewer relapses of all kinds than treatment with rest periods or lapses (continuous treatment 13.1 per cent relapse and Wassermann fastness, as against 20.8 per cent with intermittent, 45.3 per cent with irregular, and 41.5 per cent with intensive treatment)

End results after two years show even more clearly the dangers of the rest period and irregularity of treatment as well as the inadequacy of the short arsphenamine course in the intensive system. With continuous treatment, 79.7 per cent achieved satisfactory or "curative" results, with intermittent treatment (rest intervals), 65.0 per cent, with irregular treatment, 33.3 per cent, and with intensive treatment, 23.4 per cent.

PROLONGED TREATMENT, FIXED SCHEDULE AND "ABORTIVE CURES"

It has become inexcusable either to shorten treatment because the patient was seen early in the course of the infection (Wassermann negative or seronegative primary syphilis), or because his blood test, originally positive is reversed to negative within the first year. The former conception, that of so-called abortive cure, has been abandoned even in the country of its origin (Germany). The latter conception, much more widely prevalent in this country, also should be abandoned. The Wassermann reactions are an unsafe guide to the time of cessation of treatment. That the patient tends to stop with the first negative is the well known "fiscal landmark" of Harrison, and it is an open question whether, for his own good, the patient should be informed of a negative blood test even if he obtains one, lest he thereupon shorten his course of treatment. Treat by schedule and not by Wassermann test is the slogan of the best modern practice.

The failure of the blood Wassermann reaction to reverse is more a matter of how treatment is given than of how much treatment is administered. A little treatment continuously given is more than twice as effective as when intermittently applied and more than four times as effective as when irregularly given. Prolongation and intensification of treatment, however, using much arsphenamine and much heavy metal, but especially much arsphenamine in the first three months, promotes good results. Much arsphenamine and much heavy metal is four times as effective as little arsphenamine and little heavy metal in securing a negative Wassermann reaction within this period, when the drugs are continuously used. This statement is based on five or more doses in this three month period representing "much." The good end results obtained by prolonging continuous treatment for more than a year are more than double those obtained by the same kind of treatment carried through less than a year (49.7 per cent versus 24.4 per cent).

THE DANGERS OF LITTLE ARSPHENAMINE AND THE SHORT ARSPHENAMINE COURSE

The distressing frequency of the practice, for which physician or patient may be to blame, of giving four or five arsphenamine injections, testing the blood, finding the patient Wassermann negative in an early case, and virtually dismissing him with a few pills, munctions or heavy metal injections should be fought with every resource that current knowledge can bring to bear. Consider first infectious relapse. Two thirds (64 per cent) of those patients who received only

one to four injections of an arsphenamine with heavy metal relapsed, while of those who received from five to nine injections with heavy metal, only one seventh (14 per cent) relapsed. The critical point, then, for a large proportion of patients with early syphilis with respect to the control of their infectiousness lies between the fifth and the ninth arsphenamine injection. Figures already cited show that twenty injections of an arsphenamine is the approximate number a patient with early syphilis should have in order to avoid becoming a menace to family and community through infectious relapse.

In the nervous system, formerly thought to be injured by an arsenical, it appears that three times as much relapse (neurorrecurrence) and other involvement develops if little arsphenamine is administered, than if much arsphenamine is used. Here the measure "little" arsphenamine indicates less than twenty injections and "much" arsphenamine more than twenty injections.

With reference again to the fixed positive serologic bugbear, the amount of treatment given is of less importance than the manner of its administration, the superiority of continuous treatment over intermittent, intensive and irregular treatment being shown by previously cited figures.

SOME "VERSUS" DATA

The practicing physician feels himself constantly in need of advice as to the relative merits of one or another drug in the treatment of syphilis. It appears from the Cooperative Clinical Group investigation that the original arsphenamine when used alone is superior in rapidity of action on the blood Wassermann reaction, but the deficiencies of neoarsphenamine are to some extent compensated for by its use with a heavy metal and by its employment in a continuous rather than an intermittent system of treatment. Neoarsphenamine is inferior to arsphenamine in that it produces a larger residue of absolutely irreversible blood Wassermann reactions than does the older drug. The total of "satisfactory results" (in cases under treatment or observation for six months or longer) with arsphenamine is 20.7 per cent as compared with 17.5 per cent with neoarsphenamine, and the total of relapses with arsphenamine is 26.6 per cent and with neoarsphenamine is 26.7 per cent. Neoarsphenamine, although slightly inferior to arsphenamine, is not an "inefficient" drug, and its greater adaptability and easier application make it, in suitable combination, the preferred drug for the physician engaged in general practice, on whom is dependent the ultimate suppression of syphilis. These conclusions seem to carry the greater validity because they tend to reconcile the very similar results in American and European clinical practice. It should be noted, moreover, that in irregular treatment there is little choice between the two drugs. In the matter of reactions the two drugs parallel each other and given in terms of reactions per thousand injections for arsphenamine they show 14.7 for mild and 2.2 for severe reactions, for neoarsphenamine they show 13.7 for mild and 2.4 for severe reactions. These figures are based on 105,942 injections of arsphenamine and 30,779 injections of neoarsphenamine.

In early syphilis, both in the cooperative studies of relapse and in the study of the general effect of treatment, the evidence tends to indicate that the combinations of arsphenamine-bismuth are more effective than those of arsphenamine-mercury. Arsphenamine-mercury

combinations may act more rapidly than arsphenamine-bismuth combinations in the first three months in reversing the blood Wassermann reaction, but the good effect of the arsphenamine-bismuth combinations appears later (that is in the four to twelve months reversal group). Particularly in controlling infectious relapse, it appears that in arsphenamine-bismuth combinations relapses occurred in only 3.6 per cent, as contrasted with 9.6 per cent with arsphenamine-mercury combinations. However since the proof of the value of any drug lies in the clinical rather than the serologic results, and a complete clinical evaluation has not been made a final judgment on the relative merits of the two heavy metals from these studies, is premature.

OPTIMAL TREATMENT

Is it possible to define an average amount of treatment that leads to good results? On the much to be desired answer to this question, the Cooperative studies shed a certain amount of light, complicated by the statistical complexities introduced by lapse of patients lack of adequate follow up and similar influences that affect the entire field of modern syphilology. It appears that after two years of observation or treatment the largest number of patients obtaining satisfactory results falls in the category of those receiving from twenty to twenty-nine injections of an arsphenamine and a similar amount of heavy metal. Thus, thirty injections of the arsenical becomes a therapeutic objective, in place of the "forty or over" suggested by the results of earlier investigators. That heavy metal is a necessary participant in the securing of good results is indicated by the fact that progression and relapse occurred when much arsphenamine and little heavy metal was given in 25.9 per cent, as compared with 16.5 per cent of the patients who received much arsphenamine and much heavy metal (over twenty injections or 120 injections).

A SYSTEM OF TREATMENT INCORPORATING THE FOREGOING PRINCIPLES

From the data thus far presented it appears, then that the modern system for the treatment of early syphilis must be continuous, it must employ an arsphenamine and a bismuth compound the latter intramuscularly, it must call for not less than twenty and unless special resistiveness is encountered, hardly more than thirty injections of the arsphenamine, and in accordance with the principles generally recognized in the treatment of the disease the system should call for continued treatment with heavy metal for one year after all symptoms and signs of the disease have disappeared. In order to determine this end point blood tests should be taken at least at the beginning and end of each arsphenamine course and the patient should be warned of the lack of significance of the negative report from the standpoint of the schedule. Weak positives after a negative has appeared should be taken as seriously as strong or fully relapsing positives. A spinal fluid examination with Wassermann test cell count protein estimation and colloidal gold test should be made before the end of the arsphenamine phase of treatment or the introduction of any rest period (none to be allowed until after the first year). It is understood that such a system can be carried through only with adequate tolerance on the part of the patient and this tolerance should be conserved in every possible way. If it fails the case becomes one for consultation. The same system should be employed whether treatment is begun in the seronegative or seropositive primary or the secondary stage.

All standardized treatment for early syphilis should be preceded by an examination of the urine for albumin sugar and casts and by a sufficiently detailed physical examination to assure the absence of serious organic disease. Inquiry should be made as to symp-

toms of second and eighth nerve involvement recent severe headaches hepatitis (jaundice enlarged liver acholic stools) and pregnancy before the first treatment is given. If such symptoms are present, preparatory use of a bismuth compound in seropositive primary or secondary syphilis may be required. As a rule however, there are no contraindications of this sort to the scheme about to be described. As soon as possible

and at least within the first week, a complete physical, neurologic and blood serologic examination should be recorded

AN ALTERNATING CONTINUOUS ARSPHENAMINE-BISMUTH SYSTEM

The arspphenamine-bismuth alternating system here described is essentially that used in recent years by the clinics of the Cooperative Group and published in 1929 for the guidance of practitioners. In general, if neoarsphenamine is substituted for arspphenamine, a longer arsenical course and somewhat shortened intervals, with a dosage scale of 0.45-0.6 Gm maximum for women, and 0.6-0.75 Gm for men is advised.

As an optional scheme more in harmony with the trend toward longer courses three series of from ten to twelve injections each of the arsenical drugs may be given. To secure an overlapping of the heavy metal and the arsenical, believed by some observers to protect against neurorecurrences, two, three or even four injections of the bismuth compound should be given before the end of the longer arsenical course, continued through the period in which the arsenical is suspended, and on into the beginning of the next arsenical course. The bismuth compound is then suspended while the arsenical course is completed.

REACTION-PREVENTION PRINCIPLES

It is exceedingly difficult to include detail within the space of a paragraph on reaction prevention. Only certain general principles can be given. The initial physical and urine examinations have been mentioned. In addition, the following items are of moment. The physician should

- 1 Inquire into the history of idiosyncrasy, allergic tendencies, skin irritability (especially eczema and seborrhea), focal and intercurrent infection, liver damage, and pregnancy before treatment is begun.

- 2 Question the patient before each treatment regarding (a) itching skin or rash, (b) purpura and melena, (c) gastrointestinal reaction, (d) condition of the mouth and teeth.

- 3 Examine at least the eyes (jaundice), face (dermatitis), mouth (salivation, bismuth pigment, purpura), flexures of the elbows (dermatitis), wrists and ankles (purpura) before each treatment. Take the temperature.

- 4 Make the first dose of any drug not more than half the full dose.

- 5 Pull back on syringe pistons before intravenous injections to be sure of vein entry, before an intramuscular injection to be certain a deep vessel has not been entered.

- 6 Inject intramuscularly into the inner angle of the upper outer quadrant of the buttock and massage long and well after the injection.

- 7 Inject all solutions for intravenous use slowly through a small needle, not faster than 0.1 Gm per minute for neoarsphenamine.

- 8 Keep carbohydrate and alcohol low in the diet, and protein and fat high.

- 9 Permit only a light meal before and after an arsenical, and prescribe a mild cathartic the morning after.

- 10 Make a urine examination biweekly.

- 11 Give calcium freely.

PHYSICIAN-PATIENT RELATIONSHIP AND RESPONSIBILITY

The physician has it largely in his power to make or mar the outcome for a patient with early syphilis. He is responsible (1) for an adequate technic, (2) for close surveillance as to infectiousness, (3) for anonymous reporting to health authorities if his state law requires, (4) for the return of recalcitrants in the infectious stage to treatment, (5) for adequate instruc-

tion of his patient as to course, prevention of complications, and transmission of the disease, (6) for instruction as to marriage and procreation. It is, moreover, essential that he establish a rapport with his patient that will hold him to treatment for the time required. In doing this, the following guide to the substance of the first interview or two is helpful. The physician should lay before the patient the facts under these heads:

- 1 That he has syphilis and present the evidence for the statement.

- 2 His outlook for "cure" with emphasis on the excellent reward of persistence in early cases.

- 3 The general facts of infectiousness as previously outlined.

- 4 The possibility of marriage, under medical control with personal cooperation, and the possibility of healthy offspring under prenatal direction and treatment.

- 5 The necessity for postponement or avoidance of marriage, intercourse and pregnancy until the infection is under therapeutic control with the arspphenamines.

- 6 The relative inefficiency of the blood serologic tests as a measure of infectiousness, fitness for marriage or conception, and "cure" (reiterate).

- 7 The dangers (relapse, neurorecurrence, serologic irreversibility and treatment-fastness, precocious tertiarism and malignant syphilis) of inadequate, short course and irregular treatment.

- 8 The lulling into false security produced by the quick disappearance of symptoms under treatment.

- 9 The probable treatment requirements, including at least an eighteen months estimate for early syphilis, whether sero-positive or seronegative primary, or secondary.

- 10 Personal hygiene, control of treatment reactions, and symptoms of infectious recurrence.

- 11 The need for observation throughout life.

- 12 Special arrangements (examination of contacts and infection source, of family, communication of facts to others, treatment arrangements for travelers and nonresidents).

- 13 The probable costs and their settlement or adjustment.

OBSERVATION THROUGHOUT LIFE

Every effort should be made by the physician responsible for a patient with early syphilis to keep his charge under observation throughout life. This is the only assurance we can as yet offer against insidious unrecognized progression and relapse. During the probationary two years following the cessation of the standard treatment, observation and serologic tests are desirable three or four times a year. After this period, yearly physical examination and blood test, without repetition of the spinal fluid if previously twice negative, is in order. Teleroentgenographic and cardiologic study of the heart and great vessels is desirable by the fifth year, and thereafter as the physical examination indicates, but at least with repetition in the tenth year. Only by such supervision can the greatest security be insured for the patient.

Vitamin A and Epithelial Structures—One of the most characteristic properties of vitamin A is its power of influencing the development of epithelial structures in the body. In the absence of this vitamin from the diet the cells lining the respiratory, alimentary and genito-urinary passages as well as those of certain glandular organs lose their normal structure and arrangement and tend to be changed to layers and nests of keratinized epithelium. This change is of great importance for the reason that the altered epithelial surfaces permit the invasion of bacteria so that infections are more likely to occur in animals suffering from a deficiency of this vitamin in their diet. Exactly how far a plentiful supply of vitamin A will protect human beings from infections is not known.—Colwell, S. J. *Vitamins in Clinical Medicine, Practitioner* 132 15 (Jan) 1934.

AN ANTIDOTE FOR ACUTE MERCURY
POISONING

PRELIMINARY REPORT

SANFORD M ROSENTHAL, M D
Senior Pharmacologist, National Institute of Health U S Public
Health Service
WASHINGTON, D C

In experimental work recently reported,¹ sodium formaldehyde sulphyxylate has been found to afford a high degree of protection to dogs who have previously received a fatal dose of corrosive mercuric chloride by mouth. A short account of this work with the methods of study and the technic of therapy, which I have tentatively adopted for human cases, is herein given so that it may be made available for clinical use at an early date.

Several compounds were tested for their ability to counteract the effect of corrosive mercuric chloride on excised tissues. This was done by studying the oxygen consumption of rat tissues in the Warburg-Barcroft microrespiration apparatus. The compounds that yielded promising results on oxygen consumption of tissues were then tested on rats and dogs for evidence of protective action against fatal doses of corrosive mercuric chloride.

TABLE 1—Protective Action of Sulphoxylylate Therapy Against Fatal Doses of Corrosive Mercuric Chloride Administered Intravenously and Orally to Dogs *

Number of Dogs	Corrosive Mercuric Chloride	Antidote	Time Administered After HgCl ₂	Effect	
				Survived	Died
8	4 mg per Kg intravenously	None		1	7
5	4 mg per Kg intravenously	20% sulphyxylate 0.7 Gm per Kg intravenously	Just before HgCl	5	0
4	20 mg per Kg by mouth	0.8% NaCl 3 cc per Kg	4 hours after	1	3
4	20 mg per Kg by mouth	Sulphyxylate 0.5 Gm per Kg intravenously	17 to 30 min	4	0
9	2.5 mg per Kg by mouth	0.8% NaCl 2.5 cc per Kg Intravenously 5 cc per Kg by mouth	40 to 90 min	1	8
3	2.5 mg per Kg by mouth	Sulphyxylate 0.5 Gm per Kg intravenously	33 to 70 min	1	2
12	2.5 mg per Kg by mouth	Sulphyxylate 0.5 Gm per Kg intravenously 1 Gm per Kg by mouth	40 to 90 min	9	3
3	3.5 mg per Kg by mouth	0.8% NaCl 2.5 cc per Kg Intravenously	30 minutes	0	3
3	3.5 mg per Kg by mouth	Sulphyxylate 0.5 Gm per Kg intravenously	33 to 70 min	1	2

* Control dogs received equivalent volumes of 0.8 per cent physiologic solution of sodium chloride.

A summary of results obtained in dogs with sulphyxylate therapy is shown in table 1. When sulphyxylate was administered intravenously, all of five dogs survived a subsequent fatal dose of corrosive mercuric chloride (4 mg per kilogram) also injected intravenously. Preceding the oral administration of corrosive mercuric chloride, the dogs were given from 15 to 20 mg per kilogram of morphine sulphate subcu-

taneously to prevent vomiting. Four dogs were given 20 mg per kilogram of corrosive mercuric chloride by mouth and sulphyxylate intravenously from seventeen to thirty-four minutes later, with no deaths. Three of four control dogs treated with 0.8 per cent sodium chloride died. When larger doses of corrosive mercuric chloride (from 25 to 35 mg per kilogram) were given by mouth to six dogs, and sulphyxylate therapy was given intravenously up to seventy-five minutes later, only two of the six survived. In the dogs that succumbed, autopsy revealed widespread necrosis of the mucous membrane in the upper gastro-intestinal tract, while histologic examination by Dr J G Pasternack of this laboratory showed little or no pathologic changes in the kidneys as compared to the extensive degenerative changes typical of mercurial nephritis, which was found in the control dogs.

These observations suggested that the damage in the alimentary canal might have been an important factor in the death of these treated animals, since sulphyxylate administered intravenously does not appear in appreciable amounts in the alimentary canal. Accordingly, twelve dogs were given a fatal dose of corrosive mercuric chloride (25 mg per kilogram) by mouth and sulphyxylate therapy both by mouth and intravenously.

Chart 1—The absence of elevation of blood nonprotein nitrogen in nine dogs that received 25 mg per kilogram of corrosive mercuric chloride by mouth and oral and intravenous sulphyxylate therapy within an hour and a half. Interrupted lines represent control dogs; continuous lines, treated dogs.

within an hour and a half after the mercury. Nine survived, and a striking result found in these animals was the high degree of protection against kidney damage, as shown by the lack of elevation of nonprotein nitrogen in the blood for two months subsequent to the intoxication (chart 1).² Of the three treated dogs that succumbed, two died during the first night. At autopsy no renal lesions were present. The third lived eight days but refused all food during this time. Bloody stools were present. In spite of the elevation of nonprotein nitrogen that occurred in this dog, careful histologic examination of the organs showed only some inflammatory changes in the gastro-intestinal mucosa. Autopsy also revealed that this animal was pregnant.

Ten control animals were given corrosive mercuric chloride, 25 mg per kilogram, by mouth and treated with 0.8 per cent sodium chloride in equivalent amounts. Nine of the dogs died, and it is believed that vomiting occurred in the survivor, since little elevation of the nonprotein nitrogen occurred. Marked renal lesions were present in these nine dogs and elevation of nonprotein nitrogen in those animals studied.

1 Rosenthal S M. Experimental Studies in Acute Mercurial Poisoning. Pub Health Rep 48: 1543 (Dec 29) 1933.

2 Rabbits given two times the fatal dose of corrosive mercuric chloride subcutaneously can be completely protected against kidney damage by intravenous injections of sulphyxylate.

The basis of this protective action against corrosive mercuric chloride by formaldehyde sulphoxylate has been studied from the point of view both of chemical characteristics and of pharmacologic behavior. Sulphoxylate is a strong reducing agent and can rapidly reduce indigo carmine, whose reduction potential at p_H 7.0 is -0.125 volt. It can confer this reducing action to the body fluids and excretions, other possible applications of this alternation of reducing power in the body, physiologic as well as therapeutic, are being investigated.

The ability of sulphoxylate to reduce corrosive mercuric chloride into the insoluble and less toxic mercurous salts and to metallic mercury is marked. A grayish black precipitate can be detected when a few drops of 1 per cent corrosive mercuric chloride is added to aqueous solutions of sulphoxylate up to one part in 400,000. Likewise, a precipitate can be detected when a few drops of 1 per cent sulphoxylate is added to corrosive mercuric chloride solutions up to one part in 80,000. Following intravenous injections into animals, the ability of the blood serum to reduce corrosive mercuric chloride is the most sensitive test that has been developed for the detection of sulphoxylate. If 0.1 cc of 0.2 per cent corrosive mercuric chloride is

Chart 2—Curve 1 the excretion of formaldehyde sulphoxylate in the urine of an unanesthetized dog of 10 Kg following the injection of 2 Gm of sulphoxylate intravenously. Curve 2 urinary excretion in a rabbit of 3.4 Kg following the intravenous injection of 17 Gm of sulphoxylate.

added to 0.5 cc of blood serum, normally no precipitate results. Following intravenous injections of from 0.5 to 1.0 Gm per kilogram of sulphoxylate in animals, the blood serum and urine for at least five hours will show this precipitation.

The toxicity of sulphoxylate is low. One gram per kilogram of a 10 per cent solution administered slowly by intravenous injection into rats, rabbits, guinea-pigs and dogs is tolerated without symptoms. One gram per kilogram injected intraperitoneally daily for three weeks produced no visceral changes in rats as shown in histologic examinations by Dr Pasternack.

When given by mouth in doses of from 0.2 to 0.5 Gm per kilogram (10 per cent solution), no symptoms are produced except in some cases a purgative action and sulphoxylate can be demonstrated in the semisolid stools within a short time. From 5 to 10 per cent of this oral dose can be recovered in the urine. When from 0.2 to 0.5 Gm per kilogram is injected intravenously into rabbits and dogs, approximately from 70 to 75 per cent can be recovered in the urine within seven hours (chart 2). For the qualitative and quantitative estimation of sulphoxylate in aqueous solutions, a color reaction has been developed that will detect one part of sulphoxylate in 8,000 and that is not

given by any of the other sulphur compounds that have so far been tested.³

To 4 cc of the dilute solution in a large size test tube, approximately 4 Gm of ammonium sulphate crystals (more than will dissolve) and 0.6 cc of a freshly prepared 2 per cent solution of sodium nitroprusside are added. The test tube is shaken frequently for five minutes, during which time a green color will develop, which fades out. The tube is allowed to stand fifteen additional minutes and then 4 drops of a 3 per cent solution of hydrogen peroxide is added. A blue color develops that is permanent for several hours. By employing a standard solution of 1 to 4,000 sulphoxylate, I have diluted the unknown solution until an approximate color match with the standard is obtained at which time the supernatant fluids can be compared in a colorimeter.

It has thus been established that (1) sulphoxylate is a compound of low toxicity that can persist in the body for several hours after intravenous injection, in concentrations that confer on the blood the ability to reduce corrosive mercuric chloride to insoluble mercurous compounds, which are known to be considerably less toxic, (2) when injected intravenously the major part of the sulphoxylate is excreted in the urine within a few hours, which means that high concentrations are reached in the kidneys, (3) following oral administration in sufficient quantities sulphoxylate can persist throughout the gastro-intestinal tract so that it can render local protection and also reduce to insoluble compounds any unabsorbed mercury that may be present, (4) a high percentage of dogs can be saved from a fatal oral dose of corrosive mercuric chloride and can be protected against renal injury if oral and intravenous therapy is given within an hour and a half after the poisoning.

The length of time after oral intoxication that sulphoxylate therapy will be of benefit remains to be established. Experiments on rats and rat tissues suggest that after the cell damage is sustained little benefit can be expected. It is likely however that following oral administration of corrosive mercuric chloride, the damage to the kidneys and other tissues proceeds for several hours, during which time sulphoxylate therapy would be of benefit. It is not possible at present to state whether this therapy will be of any benefit in the delayed symptoms of acute mercury poisoning or in chronic mercurial intoxication.

I have had occasion to administer this therapy in ten cases of corrosive mercuric chloride poisoning in human beings. The results have been confirmatory of the experimental observations and justify a report at this time in order that this therapy may be given wide spread clinical trial.⁴ The fact that no fatalities and no appreciable kidney damage occurred in any of these cases is suggestive of the value of the therapy in view of a mortality of approximately 25 per cent as reported by recent investigators⁵ and with renal injury occurring in a further percentage of the survivors. However, it is usually impossible to know the amount of

3. Sodium hydrosulphite (Na_2SO_3) has been found to give this reaction but it can be differentiated in that dilute solutions give an immediate color with nitroprusside while sulphoxylate requires the presence of ammonium sulphate.

4. The generous extension of facilities at Emergency Hospital and other hospitals has greatly aided this work. I am indebted to Dr Neil Campbell, resident physician at Emergency Hospital with whom a more detailed and extensive report will later be published.

mercury absorbed by these patients and final conclusions can be drawn only from an extensive series of cases

REPORT OF CASES

CASE 1—A man aged 26, weighing 52 Kg (114 pounds), took four 0.5 Gm tablets (30 grains) of corrosive mercuric chloride with suicidal intent. Vomiting occurred approximately an hour and a half later, and treatment was given at Emergency Hospital approximately two hours after the poisoning. Gastric lavage was carried out with 5 per cent sulphoxylate and the grayish black reduced mercury was seen in the stomach washings. Three hundred cubic centimeters was left in the stomach part of which was vomited in half an hour. After the oral therapy 250 cc of 10 per cent sulphoxylate was administered intravenously, the injection being slowly given over a period of forty minutes. Bloody stools were passed during the next twenty-four hours and the urine contained a faint trace of albumin, but subsequent blood and urine examinations at Gallinger Hospital were negative and recovery was uneventful.

CASE 2—A woman, aged 24 weighing 45 Kg swallowed two 0.5 Gm tablets of corrosive mercuric chloride. Milk and eggs were given in about fifteen minutes. Half an hour after the poisoning abdominal cramps and severe vomiting began. She was brought to Georgetown Hospital at this time where

TABLE 2—Absence of Renal Injury in Human Cases of Poisoning with Corrosive Mercuric Chloride Treated with Formaldehyde Sulphoxylate*

Case	Stated Dose of HgCl ₂ Gm	Emesis Interval	Sulphoxylate Therapy Interval	Albuminuria	Blood Nonprotein Nitrogen Mg per 100 Cc
1	20	90 minutes	120 minutes	Very faint trace negative	15†
2	10	70 minutes	420 minutes	++ negative	26-29
3	15	Short time	120 minutes	Very faint trace	26-26
4	15	30 minutes	120 minutes	Very faint trace negative	20
5	20	20 minutes	90 minutes	Trace negative	26

gastric lavage was done. She was seen by me seven hours after the poisoning when 10 Gm of sulphoxylate was given by mouth in iced orange juice. This was largely vomited within ten minutes. Ten grams of sulphoxylate was given intravenously as a 7 per cent solution in water. No symptoms were experienced during the injection and there was no change in the pulse or respiration. The blood serum two and a half hours after the injection was moderately positive for sulphoxylate (corrosive mercuric chloride test). With the exception of albumin in the urine for three days, no other effects were noted and no elevation of the blood nonprotein nitrogen occurred.

CASE 3—An obese woman aged 54 took three 0.5 Gm tablets of corrosive mercuric chloride dissolved in water. Vomiting occurred in a short time. About an hour later an emetic was given by an ambulance physician and she was brought to Emergency Hospital where gastric lavage and milk were administered. Two hours after the poisoning 10 Gm of sulphoxylate was administered by mouth in iced orange juice and 16 Gm (7 per cent solution) was slowly administered intravenously, about thirty minutes being taken for the injection. Part of the oral dose was vomited shortly after it was taken. The blood serum was positive for sulphoxylate (corrosive mercuric chloride test) three hours after the injection and the urine collected and kept on ice for fourteen hours after the therapy, contained by the colorimetric method 65 per cent of the sulphoxylate that was injected. Recovery was uneventful with no elevation of nonprotein nitrogen of the blood. The

urine from the beginning contained a very faint trace of albumin, but the past history suggested a mild chronic nephritis.

CASE 4—A girl, aged 18, took three tablets of corrosive mercuric chloride dissolved in a glass of water. She collapsed on the street and was brought to Emergency Hospital by a cab driver approximately an hour and a half after she had taken the mercury. Gastric lavage with 5 per cent sulphoxylate was given and 10 Gm left in the stomach. The stomach washings showed the presence of mercury. A considerable part of the sulphoxylate was later vomited. Twelve grams of a 7 per cent solution was given intravenously, half an hour being allowed for the injection, and three hours after this a second injection of 8 Gm was administered. The blood serum was positive for sulphoxylate (corrosive mercuric chloride test) three hours after the last injection and the urine for twelve hours after the therapy contained 65 per cent of the amount of sulphoxylate injected intravenously. A very faint trace of albumin was present in the urine for three days. Although she left the hospital against advice on the fifth day, she was symptom free and no evidence of kidney damage was present. A later report stated that she was well after leaving the hospital.

CASE 5—A man, aged 35 weighing 60 Kg, with a history of acute nephritis with edema four years previously, took four undissolved 0.5 Gm tablets of corrosive mercuric chloride. He vomited in about twenty minutes. At Emergency Hospital gastric lavage was administered with milk and eggs about an hour later, and 10 Gm of sulphoxylate by mouth and 10 Gm intravenously about an hour and a half after the poisoning. A colitis developed the following day and persisted for nine days, with from three to six liquid bloody stools daily. During his twenty-five day stay in the hospital the urine showed a trace to a very faint trace of albumin, and a few granular casts were present during the first half of this period. Phenolsulphonphthalein tests and blood chemistry gave results within normal limits. A severe mercurial stomatitis developed on the fifth day and had not completely cleared up at the time of his departure. Otherwise he left the hospital symptom free.

CASE 6—A woman, aged 26, took two 0.5 Gm tablets of corrosive mercuric chloride. Vomiting occurred in about thirty minutes. Gastric lavage with milk was given at Emergency Hospital in about ninety minutes and mercury was demonstrated in the stomach washings. Sulphoxylate therapy was administered in about two hours. Ten grams was given by stomach tube, most of which was later vomited. Thirteen grams was injected intravenously, thirty minutes being allowed for the injection, an additional 6 Gm was injected six hours after the poisoning. The blood serum four hours after the first intravenous injection was still slightly positive for sulphoxylate (corrosive mercuric chloride test). The total urine for the first twelve hours (kept on ice) contained 67 per cent of the amount of sulphoxylate given intravenously. A very faint trace of albumin was present in the urine for three days, but the blood chemistry was normal and later urinalyses were negative. She was symptom free when she left the hospital after one week, refusing to remain longer.

CASE 7—A man, aged 37, stated that at 5:30 p.m. he took two undissolved 0.5 Gm tablets of corrosive mercuric chloride. At 6 o'clock he took five potassium permanganate tablets and at 6:30 he took 2 ounces (60 cc) of tincture of iodine. Vomiting occurred after taking the iodine. He was picked up in collapse by the ambulance at 7 o'clock and brought to Emergency Hospital. Gastric lavage with milk was administered. Examination showed an iodine stain on the fingers, redness of the mouth and abdominal tenderness. From 8:30 to 9 o'clock he was given 10 Gm of sulphoxylate by mouth and 10 Gm intravenously. Examination of the urine was strongly positive for iodine and qualitative tests were negative for manganese. Quantitative examination showed the probable presence of a trace of mercury (0.8 mg per liter). No elevation of blood nonprotein nitrogen and no urinary abnormalities were present during his six days stay in the hospital when he left against advice. There was no colitis.

CASE 8—A woman aged 38 swallowed two undissolved tablets of corrosive mercuric chloride. She was brought to Emergency Hospital in forty-five minutes. Vomiting had not occurred and a considerable amount of blue fluid containing

corrosive mercuric chloride was recovered by gastric lavage. She was given 10 Gm of sulphoxylate by mouth in iced orange juice and 10 Gm intravenously an hour after the poisoning. Because of vomiting, most of the oral dose was not retained as well as a second oral dose of 10 Gm administered four hours later. Frequent bloody stools were passed during the following three days and tests for occult blood were still strongly positive on the fifth day, although no gross blood was seen. The blood nonprotein nitrogen was normal the day after admission. The urine contained a very faint trace of albumin for three days but was negative on the fifth day, when she left the hospital against advice.

CASE 9—A woman, aged 31, took an undissolved 0.5 Gm tablet of corrosive mercuric chloride. Vomiting did not occur and she was given gastric lavage with milk and eggs at Emergency Hospital within about thirty minutes. Corrosive mercuric chloride was demonstrated in the stomach washings by the grayish black reaction with sulphoxylate. Gastric lavage with 5 per cent sulphoxylate was administered in eighty minutes, 5 Gm being left in the stomach. Ten grams was injected intravenously. Later observation at Gallinger Hospital showed albuminuria for two days after which urinalysis gave negative results and blood urea nitrogen was normal.

CASE 10—A moderately obese woman, aged 37, drank about half of a 0.5 Gm tablet of corrosive mercuric chloride dissolved in water. Milk and eggs were given shortly afterward and vomiting occurred in about thirty minutes. At Emergency Hospital ninety minutes after the poisoning she was given gastric lavage with 5 per cent sulphoxylate, and 10 Gm was left in the stomach. Most of this was vomited. Ten grams was given intravenously, twenty-five minutes being allowed for the injection. Five grams was then given by mouth in iced orange juice, and this was retained. The stools for two days were strongly positive for occult blood, and the urine showed a very faint trace of albumin, otherwise she was symptom free. The phenolsulphonphthalein excretion in two hours (intravenous method) was 77 per cent at the end of a week's stay in the hospital.

Besides the fact that these acute cases of poisoning were treated as early as possible, these experimental studies emphasize the importance of certain conditions attending this therapy. It is desirable to have sufficient sulphoxylate retained in the stomach so that some of the unchanged drug will pass down the alimentary canal. If vomiting is severe, the use of morphine hypodermically may be helpful. If little of the drug is retained the use of high colonic irrigations with a 1:1,000 solution of sulphoxylate is indicated. The other requirement is to give sufficient amounts of the drug intravenously to confer on the blood for several hours the ability to reduce corrosive mercuric chloride, as described. To this end, in the average adult human case the following procedure is suggested.

Gastric lavage is done through a stomach tube with a 5 per cent solution of sulphoxylate, approximately 200 cc of this solution being left in the stomach. Immediately following this, 10 Gm dissolved in from 100 to 200 cc of distilled water⁶ is slowly injected intravenously, from twenty to thirty minutes being permitted for the injection. From four to six hours after the completion of this injection the intravenous administration of from 5 to 10 Gm of sulphoxylate may be repeated in severe cases. If it is feasible to test the blood serum against corrosive mercuric chloride, the time that this reaction becomes faintly positive or negative (from three to five hours) may be taken as an indication of the time to give this second intravenous

dose of sulphoxylate. If colitis later develops, I employ high colonic irrigations with a 1:1,000 solution of sulphoxylate once or twice daily.

SUMMARY

Sodium formaldehyde sulphoxylate saved nine of twelve dogs from a fatal oral dose of corrosive mercuric chloride, when administered by mouth and intravenously within an hour and a half after the poison had been taken. The nine surviving animals were protected against kidney damage, as shown by the lack of elevation of the blood nonprotein nitrogen. In the dogs that succumbed following this therapy or following intravenous therapy only, no significant renal lesions were demonstrable histologically.

The sulphoxylate was used in ten human cases of acute poisoning from corrosive mercuric chloride, and recovery occurred without appreciable kidney damage.

HYPERPARATHYROIDISM

A COMMON AND POLYMORPHIC CONDITION AS
ILLUSTRATED BY SEVENTEEN PROVED
CASES FROM ONE CLINIC
FULLER ALBRIGHT, MD
JOSEPH C AUB, MD
AND
WALTER BAUER, MD
BOSTON

Since the epoch making discovery in 1925 by Mandl¹ in Vienna and in 1926 by Du Bois² in this country that osteitis fibrosa cystica is a manifestation of hyperparathyroidism the medical profession has been quick to apply this knowledge, and the literature of the past few years contains numerous case reports and metabolic studies on this, the classic form of hyperparathyroidism. There have been, in addition, excellent summary articles on the subject.³ Most of the cases of hyperparathyroidism so far in the literature have represented the classic form, i. e., osteitis fibrosa cystica. This type of the disease is rare and offers no diagnostic difficulties. It is one of our chief objects in the present paper, however, to point out that other forms of hyperparathyroidism are not rare pathologic curiosities but conditions that every practitioner will not infrequently meet. The diagnosis must be considered and ruled in or out when any of a whole list of presenting symptoms of the most varied nature is encountered. The seventeen cases that form the basis of this paper were all studied at the Massachusetts General Hospital and a parathyroid tumor was removed in each instance. Of these cases, eleven were so diagnosed for the first time at this hospital. The large series can be only partially accounted for, therefore, by the fact that a special study on bone metabolism was being conducted. Only the clinical points of value to the practitioner will be emphasized in this paper, stress being laid on the early symptoms and the diagnosis or exclusion of the disease.

From the Medical Service of the Massachusetts General Hospital. The data on two patients are supplemented by those obtained at the Huntington Memorial Hospital.

⁶ Commercial samples of technical sodium formaldehyde sulphoxylate are impure and are not suitable for intravenous injection. A purified product should be used and the solutions should be freshly prepared. Preparations of the drug suitable for this purpose and sealed in ampules with the exclusion of oxygen may be obtained from manufacturers of neosarsphenamine. We are indebted to Merck & Co., New York, the Diarsenol Company, Inc., Buffalo, and the Dermatological Research Company, Philadelphia, for a supply of these ampules.

In tables 1 and 2 the cases are arranged chronologically with reference to the date of removal of the tumors, and the more important features are tabulated

PATHOLOGY

Metabolism—Hyperparathyroidism is a disease that is usually due to a functioning adenoma of the parathyroid glands. Cases 15, 16 and 17 in this series however presented hyperplasia of all parathyroid tissue. This aspect will be discussed in another communication. As a result of the increased production of the hormone, there is a disturbance in the metabolism of calcium and phosphorus. The easily measurable manifestations of this disturbance are an increased serum calcium level, a decreased serum phosphorus level, and an increased excretion of both elements in the urine.

Bones—The bones are the only storehouse for calcium and phosphorus in the body, so that this increased loss in the urine, other things remaining equal, leads to a demineralization of the bones. The histologic evidence of an increase in calcium absorption is an increase in osteoclasts. The bones, therefore, become porous and filled with osteoclasts. Osteoblasts, laying down new bone, attempt to keep pace with the osteoclasts and are therefore likewise increased. Both these cells are derived from the reticular cells of the bone marrow. The fibrosis that occurs probably represents a proliferation of the reticular cells to form the osteoblasts and osteoclasts. Two additional secondary changes may occur. Cysts may develop in the fibrous areas and enlarge until they form multiple cysts with fibrous walls. Secondly, the osteoclasts in certain areas may proliferate to such a degree that they form osteoclastomas (benign tumors of bone tissue with giant cells). The disease at this advanced stage with cysts and tumors was described by von Recklinghausen in 1891⁴ and has gone by the name of *ostitis fibrosa cystica multiphasata* or von Recklinghausen's disease of bone ever since.

Urinary Tract—The increased excretion of calcium and phosphorus in the urine not infrequently leads to the formation of urinary calculi (twenty-three times in a series of eighty-three cases⁶). In some instances the calcium phosphate precipitates occur in the kidney parenchyma (most often in the collecting tubules) and lead to secondary kidney contracture and insufficiency.

In case 9 in the present series, a flat roentgenogram of the abdomen revealed in the region of each kidney stellate groups of punctate shadows outlining the kidney pyramids. This observation gave the clue to the proper diagnosis.⁶

Blood—The replacement of so much of the marrow cavity with fibrous tissue leads to a decrease in the hematopoietic elements and hence in an occasional case to an anemia and leukopenia. Thus patient 1 of this series had on admission a red blood cell count of 2,400,000, a hemoglobin of 50 per cent, and a white blood cell count of 3,100.

Teeth—The teeth do not take part in the generalized decalcification. They may fall out because of disease of the jaws but they themselves remain well calcified.

This is brought out strikingly by roentgenograms in which the well calcified teeth stand out sharply against the poorly calcified jaws. This failure of the teeth to become decalcified is strong evidence against their being a reserve supply of calcium.

CLINICAL TYPES OF DISEASE

Depending on whether the urinary tract or skeletal involvement predominates and the degree of change present in each system, it is possible to describe several different types of the disease.

Classic Hyperparathyroidism (von Recklinghausen's disease)—Skeletal symptoms predominate and consist of decalcification, cysts, tumors and, eventually, fractures (five cases in this series).

Osteoporotic Form of Hyperparathyroidism—Presenting symptoms are due to generalized decalcification and there are no cysts or tumors (two cases in this series).

Hyperparathyroidism with Nephrolithiasis—Presenting symptoms are associated with renal stones and there may be no gross skeletal changes (eight cases in this series).

Hyperparathyroidism with Renal Insufficiency (nephrocalcinosis)—The symptoms are those of Bright's disease (one case in this series).

Acute Parathyroid Poisoning—This is a condition simulating acute parathyroid poisoning in dogs with sudden death and characteristic pathologic changes (no cases in this series). A case reported by Dawson and Struthers⁷ may well fall into this group.

Hyperparathyroidism Simulating (or Complicated by) Paget's Disease—The existence of this group is not yet certain. There is a discussion of this condition under the section on differential diagnosis (one case in this series).

DURATION OF DISEASE

Whereas the disease may produce a fatal issue—usually from renal involvement—it probably smolders on for years in the majority of cases, crippling but not killing. In any one case it is difficult to say just when the disease began. Patient 6 was first seen and the diagnosis was made in 1926. He had been passing gravel in the urine for eight years at that time. The tumor of case 1 appeared in the patient's neck following a miscarriage fourteen years before her admission to the hospital whereas the bone symptoms had been of only one year's duration. In this connection, case 10 is extremely interesting.

A woman aged 54 entered the hospital to have a bladder stone removed from a trabeculated "cord bladder." The cord injury had occurred as the result of a fracture of a lumbar vertebra at the age of 15. The fracture was brought about when she attempted to lift a heavy load to her head "in the old country." No further skeletal symptoms developed. If one reconstructs the story it is probable that the fracture was the result of a decalcified vertebra due to hyperparathyroidism but that this had not caused further obvious damage until it had occasioned a bladder calculus. Following the removal of the parathyroid tumor thirty-nine years after the fracture the patient stated that she had never felt so well in her entire life.

SYMPTOMATOLOGY AND PHYSICAL OBSERVATIONS

The symptomatology can be divided into three groups: (a) that due to the hypercalcemia per se; (b) that related to skeletal changes, and (c) that related

Remainder of tumor was removed and blood values are now normal

to the increased excretion of calcium and phosphorus in the urine

Symptoms Due to Hypercalcemia—Just as hypocalcemia causes an increased excitability of nerve-muscle apparatus (tetany), so hypercalcemia causes the opposite. It takes more electricity to cause a muscular contraction in such individuals than in the normal. This is the antithesis of Erb's sign for tetany. However, from a practical point of view such evidence is unreliable and superfluous. Hypotonia, lassitude, constipation and other similar manifestations are often present and are related to this effect of hypercalcemia. Flatfoot, a very common symptom, is probably related to the hypotonia. Case 2 was diagnosed as hypochondriacal and neurasthenic because of these symptoms. They all disappeared after operation. Case 1 is interesting in this respect. As already stated, fourteen years before admission the patient developed what later was proved to be a parathyroid tumor in the neck. About this time she lost her appetite and her weight fell from 145 pounds to 94 pounds (from 65.8 to 42.6 Kg). Constipation developed and she became so tired that she could not do her housework. All these symptoms disappeared immediately after operation and one year thereafter her weight was 139 pounds (63 Kg). It is characteristic of these vague symptoms that their having been present becomes obvious only after they have disappeared. The change is then commented on by the patient.

Symptoms Due to Skeletal Involvement—These symptoms vary in severity from the case showing absolutely no bone symptoms (cases 5, 12, 13, 15, 16 and 17) to one like case 6 in which the skeleton became practically nonexistent and which, in fact, may end fatally from the sheer inability to raise the thorax in respiration. A spontaneous fracture is often the event that first calls attention to the underlying disease. Bone tenderness and bone pain, usually attributed to arthritis, neuritis, and the like have in most instances been present long before. Bone deformity is usually a late manifestation except as regards the spine.

Loss of 7 inches (18 cm) in height with kyphosis was complained of by patient 6 when first seen. Bone tumor due to an underlying cyst may be an early manifestation. It is especially apt to occur in the jaw and may be treated as an epulis for years before the underlying condition is recognized (case 11). Patient 1 complained of lumps on her right forearm and one of the right metacarpal bones. Biopsy of the former showed it to be an osteoclastoma.

Symptoms Related to Hypercalcemia and Hyperphosphaturia—Polyuria and polydipsia are present in almost all cases and are usually attributed to the increased excretion of calcium and phosphorus (compare the analogy with glycosuria and polyuria in diabetes mellitus). This symptom was so prominent as to suggest diabetes insipidus in two cases.⁸ Enuresis was present in case 3 before the operation. Patients 12 and 13, both of whom had multiple urinary calculi, did not have polyuria. Had they had it, perhaps calculi would not have developed.

Renal colic or some other manifestation of nephrolithiasis may be the first and only symptom. The first symptoms in case 6, years before the diagnosis was made, was the passage of "sand" at the end of urination. Ten cases in our series have presented urinary

calculi, in seven, the symptoms were confined to those pertaining to calculi, in five of these (cases 12, 13, 15, 16 and 17), no evidence of bone disease could be discovered by roentgenograms, in the other two, it was minimal. Patient 3 had all the symptoms, signs and laboratory manifestations of Bright's disease. Had she not had bone disease as well, chronic glomerular nephritis would have been a justifiable diagnosis. Three other patients (4, 6 and 9) had definite renal impairment, presumably due to calcium deposits in the kidneys (nephrocalcinosis). In cases 4 and 9 these deposits were visible by x-rays.

The question naturally arises why some individuals with the disease develop bone lesions without lesions of the urinary tract and why others do the opposite. The explanation is probably as follows. The amount of bone disease is proportional to the daily loss of calcium phosphate from the body times the duration of the disease. The daily loss in turn is dependent on the output in the urine (proportional to the severity of the disease) plus the output in the feces (a relatively unimportant value) minus the intake in the food. Therefore, short duration together with a naturally high intake of calcium would make marked bone disease unlikely. The precipitation of calculi in the urinary tract on the other hand, will depend on the excretion of calcium and phosphorus in the urine (proportional to the severity of the disease), the alkalinity of the urine, the degree of polyuria, and the like. A severe degree of hyperparathyroidism could, therefore, be associated with calculi in a short time.

Cases 5, 10, 12, 13, 14, 15, 16 and 17 were discovered as a result of doing routine calcium and phosphorus determinations on all patients with urinary calculi. From the few patients thus far examined, we are inclined to believe that hyperparathyroidism will turn out to be a fairly common cause of urinary stone and that in the future the case in which there is a stone and no bone disease will be the commoner type of hyperparathyroidism.

X-RAYS

Skeleton—There may be no skeletal changes in hyperparathyroidism demonstrable by x-rays (cases 12, 13, 15, 16 and 17). The chief roentgen evidences, when such exist, are increased radiability, deformities, cysts, tumors and fractures. Only the first of these is fundamental, the other four are secondary changes. Being a metabolic disease, hyperparathyroidism must exert its fundamental action, demineralization, on the entire skeleton if at all. Therefore, in a doubtful case it is essential to decide at once whether one is dealing with a generalized or a localized disease.

Furthermore a disease may be polyostotic without being generalized. It must be emphasized that at first sight the secondary bone changes—cysts, tumors and fractures—may make one think that the skeleton is involved in a spotty manner, but a more detailed study will reveal that the decalcification is uniform and generalized. Of course, immobilization due to a fracture may enhance the decalcification in the involved part.

Of interest in this connection is the following case, which was referred to this clinic for a question of parathyroid disease. The patient had pains in the bones of her legs. These by x-rays showed marked increased radiability, but the upper extremities were not similarly involved. This was strong evidence against the diagnosis, which was satisfactorily ruled out on other grounds. Absence of the lamina dura in the tooth

⁸ Allan F. N. Hyperthyroidism. Proc. Staff Meet. Mayo Clinic, 6: 684 (Nov. 18) 1931. Rosenback and Disque. Verhandl. d. Ges. f. Verdaungs- u. Stoffwechselkr., tenth day, Budapest, 1930, p. 223.

sockets by x-rays has been emphasized by Strock⁹ and is a manifestation of this generalized decalcification. It is not pathognomonic of decalcification due to parathyroid disease. Therefore, given bone lesions detected by x-rays, they are presumably not due to hyperparathyroidism unless generalized increased radiability is present. An exception to this statement in the form of the disease simulating Paget's disease will be discussed under differential diagnosis.

Deformities demonstrable roentgenographically may be very extensive and obvious. Lateral roentgenograms of the lumbar vertebrae often disclose biconcave disks (fish-bone vertebrae), which occur because the softened vertebrae can no longer withstand the tendency of the nucleus pulposus of the intervertebral disk to expand. They are evidence of softened vertebrae and are not pathognomonic of hyperparathyroidism but may occur in osteomalacia, multiple myeloma and the like.

The cysts, if present, are usually multiple but need not be. There may be marked expansion of the overlying bone. A cortical cyst is especially suggestive of this disease.

The tumors or osteoclastomas usually occur in the jaws, at the ends of the long bones or in the ribs. In contradistinction to the cysts, they occur only where there is cancellous bone. As yet we know of no way, roentgenographically, of differentiating these from the cysts, unless they give the definite soap bubble appearance of such tumors.

Fractures, when present, usually occur through cysts or tumors.

In addition to these roentgenographic changes, some cases show peculiar lesions in the terminal phalanges. Patients 3 and 6 had marked soft tissue clubbing, and the latter of these patients had partial resorption of the bodies of the terminal phalanges. In case 9 the phalanges and metacarpals gave a peculiar appearance by x-rays, in that the edges of the bones were everywhere fenestrated suggesting a complete lack of cortex.

Urinary Tract—Urinary calculi or punctate deposits of calcium in the kidney parenchyma should be looked for in cases of questionable hyperparathyroidism.

The Parathyroid Tumor—Before operation, an effort should be made to localize the position of the tumor. In two cases in our series, it was visible in the anterior mediastinum by roentgenograms, although this fact was determined only after operation. The tumor often lies in close proximity to the esophagus, so fluoroscopy during the administration of thick barium by mouth might be of help. If this had been done in case 4, an unnecessary operation might have been avoided. No tumor was found at the first exploration. Two years later it was found lying wedged between the esophagus and the trachea.

LABORATORY DATA

Serum Calcium and Serum Phosphorus—Once the diagnosis is suspected, its confirmation or exclusion depends on the chemical laboratory. Hyperparathyroidism is almost unique in giving the combination of a high serum calcium and a low serum phosphorus level. Other conditions, such as multiple myeloma and metastatic malignancy, may produce a high serum calcium, but when they do, the serum phosphorus also is usually elevated. Rickets and osteomalacia are often associated with a low serum phosphorus but in these diseases the calcium is seldom above normal, more often below and never as proportionately high as the phosphorus is low.

The serum should be taken fasting. One cannot be too careful about having chemically clean syringes and centrifuge tubes. All hospital linen that might be used in drying the glassware must be avoided, as the bleaching materials contain calcium. The methods we have employed are, for the calcium, that of Fiske and Logan¹⁰ and, for the phosphorus, that of Fiske and Subbarow.¹¹ A serum phosphorus below 3.5 mg per hundred cubic centimeters and a serum calcium above 11 mg per hundred cubic centimeters should be regarded with suspicion, especially if repeatedly obtained. The preoperative range of serum calcium in our series was from 11.5 to 16.8 mg and of phosphorus from 3.6 to 1.5. An exception to the high serum calcium and low serum phosphorus rule in hyperparathyroidism occurs when the disease has progressed to marked renal insufficiency, when one gets a higher serum phosphorus (for instance, patient 3 with a serum phosphorus of 4.7).

Urinary Calcium and Phosphorus Excretions—Whereas hypercalciuria and hyperphosphaturia are two of the most constant metabolic abnormalities of the disease from a practical clinical point of view this evidence is extremely laborious to obtain, seldom necessary and, in the borderline case, often not helpful. Thus, hypercalciuria is dependent on the hypercalcemia. If the latter is at a borderline level, the former will be as well.

Plasma Phosphatase—The plasma phosphatase level, probably an index to the degree of osteoblastic activity, is elevated in hyperparathyroidism in proportion to the amount of bone disease and independent of the degree of hyperparathyroidism. Thus, patients 10, 12 and 13 with no detectable bone disease had phosphatase levels of 4.0, 2.7 and 4.0 units, respectively (method of Bodansky,¹² in which the normal range is from 2 to 4 units), whereas patient 7, with classic von Recklinghausen's disease, had a level of 16.9 units. Following operation, the phosphatase level only gradually returns to normal over a period of months, which again suggests that it is a measure of the amount of bone disease. From what has just been said, it is obvious that a normal phosphatase level does not rule out hyperparathyroidism. Nevertheless, the determination can be useful in differential diagnosis, as is shown by the following example.

A woman, aged 23, was referred to the hospital because of multiple bone cysts and a past history of many fractures. The roentgenograms strongly suggested von Recklinghausen's disease with the one reservation that the bones which were not involved with cysts showed no generalized decalcification. The phosphatase in the plasma was not elevated.

If the large amount of bone disease present had been due to hyperparathyroidism, the phosphatase level should have been elevated. However many of the important diseases that come up in differential diagnosis have elevated phosphatase levels as well. The determination is of most value, of course, in following the progress of any one case.

Renal Stones—Since in many cases of hyperparathyroidism renal stones develop, it is often important to analyze stones obtained by operation or by spontaneous passage to see whether they are of the type

⁹ Strock M S. Personal communications to the author.

which is associated with that disease. Obviously, if the stone is the result of hyperparathyroidism, it should contain a large amount of calcium and phosphorus. Hunter³ analyzed a stone and found 24.4 per cent calcium and 8.4 per cent phosphorus. Stones in cases 6 and 12 showed the following analyses: calcium 40.5 per cent and phosphorus 2.4 per cent in case 6, calcium 18.6 per cent and phosphorus 3.8 per cent in case 12.

OPERATION

The surgical aspects of these cases will be left for a separate paper by our surgical colleagues.^{12a} A few points seem worth stressing, nevertheless.

The chief operative difficulty is in finding the tumor. Only patients 1 and 9 had palpable tumors before operation. Before undertaking this operation, a surgeon must be more than just "a good thyroid surgeon." He should know the normal and possible aberrant situations of the parathyroid glands; he must be familiar with their reddish brown color and smooth surface (in contrast to the granular surface of thyroid), he must be able to differentiate them from lymph nodes, collections of fetal fat, and thyroid lobules, and he must be prepared to continue the search, even if this leads him into the anterior mediastinum (cases 6 and 7). For the latter reason the surgeon must not undertake the operation until he is convinced by the blood chemistry that a tumor is present. There is no time like the initial operation to find the tumor.

In our experience, the surgeon can expect, given a marked degree of hyperparathyroidism, to find a sizable tumor. Thus, only patient 2 in our series had a small tumor (1 cm by 0.5 cm by 0.5 cm), but she had a minimal degree of hyperparathyroidism. This particular tumor was the only one in which the normal gland could still be seen on the periphery of the tumor. At first we believed by analogy with hyperthyroidism that a small amount of tissue might cause a marked degree of the disease. It is now quite clear, however, that the tumor tissue is no more potent per gram of tissue than normal tissue. Therefore, except in very mild cases, the surgeon need not stop at every minute body encountered. This applies to normal parathyroid bodies as well. These must in no case be removed by the surgeon, who is unable to find the tumor in the hope that some good will be done. Such practice only increases the danger of severe tetany if the tumor is later found.

Unlike thyroid adenomas, parathyroid tumors mold themselves surprisingly well into crevices, as between the esophagus and the trachea. This means that one can be very close to them and still not palpate them.

We believe that hypoparathyroidism following the removal of a tumor may be very dangerous. We have observed that the tetany is most marked in the patients with most bone disease and is probably to be attributed to this fact more than to atrophy of disuse in the remaining parathyroids. We see no objection in doing a subtotal resection of the tumor in these cases, and that is our present policy (case 11). When normal parathyroids have been removed at previous operations (cases 4, 6 and 7), this should of course be done. If a surgeon decides on this procedure, he should leave behind, with a good blood supply, a piece of the tumor considerably larger than a normal gland. The tendency, because of experience with hyperthyroidism, is to leave too little. Thus, in cases 4, 6 and 7, moderately

severe tetany developed in spite of the fact that pieces considerably larger than a normal gland were left behind. Patient 11 is the only one to date who has had a tendency for the hyperparathyroidism to recur, but the removal of the remainder of her gland should offer no difficulties.

The surgeon should keep in mind the fact that multiple parathyroid tumors do occur. This was so in cases 15, 16 and 17. The surgery in such cases is an entirely different problem and discussion will have to be postponed.

NONSURGICAL TREATMENT

We believe there is no successful treatment of this condition other than surgery.

Röntgen Therapy—We followed the total calcium and phosphorus metabolism for a long period of time in patient 4, who received maximum doses of x-rays over the neck region without detecting any change in the urinary excretions or blood values, and subsequently a parathyroid tumor with no degenerative changes was removed. Patient 6 also received roentgen treatment without benefit. Treating the tumors of the skeleton with x-rays should also be avoided. Whereas it will cause temporary benefit to the tumors, it will not affect the cysts and will tend to increase the fibrosis of the marrow and enhance the anemia. Patient 8 received roentgen treatment of the right ilium when the lesion there was suspected of being sarcoma, with subjective relief.

Dietary Treatment—A high phosphate diet,¹³ a high calcium diet,¹⁴ or preferably both, will prevent decalcification. In case 4, we were even able to demonstrate a marked improvement of the skeleton by diet alone. In this case, however, kidney complications soon developed. The high calcium diet and especially the high phosphate diet increase the danger of kidney complications. Therefore, whereas dietary treatment may cure the skeleton, it does not prevent kidney damage and is to be avoided.

Vitamin D—Vioosterol in large amounts was administered to patients 1 and 4, during which time careful metabolic studies were done, and no appreciable effect on the calcium or phosphorus balances was noted.¹⁵

POSTOPERATIVE COURSE

Starting in the first few hours after the tumor is removed there is a marked decrease in the output of urine and in the excretion of calcium and phosphorus. The patients may become practically anuric. The calcium and phosphorus excretions in the urine remain low for a long period, from weeks to months. Thus patient 1 on a low calcium diet excreted in the urine during a three-day period before the operation 662 mg of calcium and 1,176 mg of phosphorus. During the second week after the operation, the corresponding figures for a three-day period were 27 mg of calcium and 122 mg of phosphorus. The serum calcium likewise responds extraordinarily rapidly. In case 9 the serum calcium in the first four hours dropped from 16.4 mg to 13.4 mg and reached 11.7 mg within twelve hours. There is a temporary slight fall of the

already low serum phosphorus as well. In table 3, post-operative values for serum calcium, serum phosphorus and plasma phosphatase and the like for case 9 are given.

Tetany may develop if the blood calcium falls much below 7 or even 8 mg. The sudden change from a high blood calcium to a low one may cause visual disturbances and may affect the mental equilibrium. Such

excess of 11.9 mg and phosphorus of 2.8 mg per hundred cubic centimeters had a calcium of 9.8 mg and a phosphorus of 3.9 mg seven hours after the removal of the tumor and, six days later, the values were 10.5 and 3.9, respectively. These are to be compared with the figures in case 9 (marked bone demineralization), which did not show normal values until almost four months after operation (table 3).

TABLE 2—Data Relating to Operative Observations and Postoperative Course

Cases	Pertaining to Operation			Immediate Post operative Course			Results at Last Examination					Evidence of Improvement
	Location of Tumor	Size of Tumor (cm)	Total or Subtotal Resection	Post operative Tetany	Serum		Time Followed Months	Serum		Plasma Phosphatase Bodansky Units		
					Calcium Mg per 100 Cc	Phosphorus mg per 100 Cc		Calcium Mg per 100 Cc	Phosphorus mg per 100 Cc			
1 M S	Below right thyroid lobe	6.5 × 5.0 × 3.5	Total	0	7.6	3.6	32	9.4	3.4	2.38	Gain of 38 pounds all symptoms gone no anemia x-rays showed increased density but cysts still unchanged	
2 M L	Usual location of right lower parathyroid	1.0 × 0.7 × 0.5	Total	0	10.4	4.4	18	10.6	3.7	1.7	Gain of weight increased strength no back pain very optimistic	
3 C E S	Behind right lobe of thyroid between esophagus and right common carotid	2.2 × 1.7 × 1.0	Total	+++ cataracts	5.3	5.0	13				Increased density of bones by x-rays kidney function tests not repeated, albuminuria still massive*	
4 N B	Behind esophagus at level of thyroid gland	3.5 × 2.0 × 1.0	Subtotal	+	5.8	4.3	12	7.6	4	3.0	Gain in weight of 25 pounds symptom free	
5 R T	Below lower right pole of thyroid	1.5 × 1.0 × 1.0	Total	+	8.8	1.9	No follow up

9 J R C	Below and posterior to left lobe of thyroid adjacent to esophagus	4.0 × 2.2 × 2.0	Subtotal	+++	6.2	3.9	6	8.8	3.4	7	No symptoms gain of 25 pounds	
10 M J S	Posterior to left lobe of thyroid	3.0 × 1.7 × 0.8	Total	0	10.5	3.9	5	10.5	3.65	4	Gain 12 pounds in first two months feels much stronger	
11 M T	Posterior to upper half of left lobe of thyroid along side of trachea	3.0 × 2.0 × 1.0	Subtotal	+	7.2	2.2	4	11.4	2.8	5.2	Still bedridden feels stronger	
12 Y D	Below left lobe of thyroid (elena)	1.5 × 1.5 × 1.5	Total	+	8.0	3.2	0					
13 W G S	Posterior to left lobe of thyroid	1.7 × 1.7 × 1.7	Total	0	10.0	2.3	1				Increase in strength less tired at end of day's work gain of 6 pounds	
14 M R	Posterior to right lobe of thyroid (cystic)	2.2 × 1.2 × 1.0	Total	0	10.1	2.5						
15 A P	Two lower glands and right upper in normal position left upper not found all three very large	1.5 × 1.2 × 0.5 1.8 × 0.8 × 0.6 5.0 × 3.0 × 1.3	Total of two and subtotal of third	0	12.0	2.2						
16 T F	Both glands on right enlarged left side not explored	1.5 × 1.0 × 0.6 4.5 × 3.5 × 2.5	Total of two	0	10.8	2.2						
17 J M M	All four in normal positions and very large	2 × 2 × 1 1 × 0.5 × 0.4 1.8 × 1.5 × 0.4 2 × 2 × 1	Total of three resection of fourth	0	10.8	2.2						

* Since the paper was written the patient has died. Details concerning the death were not obtained but it was probably due to renal insufficiency.

patients may become temporarily very apprehensive. The treatment of the tetany is beyond the scope of this paper. If the suggestions are followed under the section entitled "operation" we believe that tetany requiring special treatment will seldom be necessary. The time required for the blood calcium and phosphorus to return to normal probably depends mostly on how much the skeleton has to be repaired. Thus patient 10 with no skeletal changes and a preoperative serum cal-

The improvement in symptomatology to be noted following operation is extraordinary. Whereas the patient's only complaint before operation may have been related to a fracture, he not infrequently says after the operation that he has not felt so well in years. A gain of weight is marked, constipation disappears, lassitude is replaced by a feeling of energy, bone pain and tenderness disappear within a few days. A bone biopsy in case 9 eight days after operation showed that

the osteoclasts had already disappeared. The rapid disappearance of bone symptoms is especially surprising in view of the fact that roentgenograms may show no decrease in the radiability for six months. The osteoclastomas gradually disappear. The cysts probably remain indefinitely. The roentgenograms in case 1, taken three years after the operation still showed the bone cysts unchanged even though all preoperative symptoms had disappeared, whereas the roentgenograms in case 4 showed marked improvement one year after operation in what was considered to be bone tumors. If the lesion, whether interpreted as a cyst or as a tumor by x-rays, improves after operation it is likely that it was a tumor. Whether the calcium deposits in the genito-urinary tract are ever absorbed we cannot state. The deposits in the kidneys in case 9 were still unchanged four months after operation, as

Senile Osteoporosis—By osteoporosis is meant a condition in which the bone tissue is quantitatively decreased but qualitatively normal. It may be brought about by an underactivity of the osteoblasts in laying down bone (senile osteoporosis) or by an overactivity of the osteoclasts in resorbing bone (osteoporotic form of hyperparathyroidism). The end result is very much the same in either case—the roentgenogram shows increased radiability, bone pain, fractures and deformities occur. The serum calcium in senile osteoporosis is normal, the serum phosphorus is reduced (often about 3 mg) or normal, the plasma phosphatase is normal. If these criteria are not sufficient to differentiate the two conditions, a bone biopsy in senile osteoporosis would fail to show fibrosis of the marrow and increased osteoclasts. In exophthalmic goiter of very long standing we have observed a generalized osteoporosis, which has

* Normal value is 63 mg. (Bauer, Waller, Albright, Fuller and Ambrose, C. Studies of Calcium and Phosphorus Metabolism in the Calcium Excretion of Normal Individuals on a Low Calcium Diet. Data on a Case of Pregnancy. J. Clin. Investigation 7: 70 [April] 1929).
† Expressed as percentage of dye excreted in fifteen minutes after intravenous administration. Normal values are 25, 15, 20, 10, 12 (Chapman, L. M. and Halsted, J. A. The Fractional Phenolsulphonphthalein Test in Bright's Disease. Am. J. Med. Sc. 186: 223 [Aug.] 1933).

was the phenolsulphonphthalein output. Patient 3 with severe kidney damage, nephrocalcinosis, showed no improvement of renal function during the first two months after operation. Such improvement, however, was shown by a patient studied by one of us (J. C. A.) at the Huntington Hospital following operation at the Peter Bent Brigham Hospital.

DIFFERENTIAL DIAGNOSIS

Just as hyperparathyroidism mimics many conditions, so many conditions mimic hyperparathyroidism. There are other metabolic diseases causing urinary calculi, gout, oxaluria, cystinuria and the like; there are other conditions causing polyuria, pain in the back, flatfoot, constipation, lassitude and the like, but our discussion here will have to confine itself to other bone diseases that are to be considered in differential diagnosis. In table 4, these are listed and the outstanding differential points are put in tabular form.

persisted for years after the thyrotoxicosis. The osteoporosis in this condition is presumably of the increased bone resorption type.

Of all the conditions to be differentiated from hyperparathyroidism, "senile" osteoporosis is perhaps the most difficult. This is because it resembles the mild osteoporotic form of hyperparathyroidism in which the blood values are almost borderline anyway. Thus, patient 2 with this form of hyperparathyroidism, had normal blood values when first seen. Only after repeated blood chemistry determinations for a year was the correct diagnosis made. Her tumor was only 1 cm. long. In such mild cases complete metabolic studies will probably still be indicated.

Paget's Disease (osteitis deformans).—In the first place, we believe that Paget's disease is not a form of hyperparathyroidism, as advocated by some,¹⁶ because

16. Ballin, Max and Morse, P. T. Parathyroidism. Am. J. Surg. 12: 403 (June) 1931. Parathyroidism and Parathyroidectomy. Ann. Surg. 94: 592 (Oct.) 1931.

(1) although often polyostotic it is never generalized, which is almost inconceivable for a metabolic disease, (2) in Schmorl's entire series of 138 personally observed autopsies,¹⁷ in six cases studied by Stenholm¹⁸ and in one case recently from this clinic in which an autopsy was performed, the parathyroid glands showed no significant histologic changes, and (3) the metabolic changes are not those of hyperparathyroidism.¹⁹ It must be stated that a biopsy taken from an advancing edge of a Paget's disease lesion may be extremely difficult to distinguish from osteitis fibrosa cystica. Roentgenograms usually serve to differentiate the two diseases. In Paget's disease, in contradistinction to osteitis fibrosa cystica, one notes the spotty distribution

comparable degree of bone disease, is considerably higher than that observed in osteitis fibrosa cystica. The two diseases have little in common, therefore, and this is true of the majority of cases. In spite of these facts, we have included under the clinical types "hyperparathyroidism simulating [or complicated by] Paget's disease." We cannot define the exact connection if any, between the two diseases at the present time. The facts are these: Patient 8 had symptoms localized to one bone, the roentgen changes of the skeleton aside from slight generalized decalcification were localized to the same bone (right ilium); the roentgen changes themselves could be considered consistent with Paget's disease, the blood chemistry

TABLE 4—Points in Differential Diagnosis Between Hyperparathyroidism and Other Bone Diseases

Disease	Differential Points as Regard			Serum		Plasma Phosphatase	Miscellaneous
	Symptoms	Roentgen Studies	Biopsy	Calcium	Phosphorus	High	
Hyperparathyroidism with bone involvement	Bone pain & deformity fracture tumor polyuria those related to stones	Increased radiability generalized deformity cysts tumors fractures stones	Rarefied bone fibrosis of marrow osteoclasts +++ osteoid tissue only slightly increased osteoblasts +++	High	Low	High	All age groups
Senile osteoporosis	No bone tumor polyuria or stones	No cysts tumors or stones	No fibrosis of marrow osteoclasts normal osteoid tissue normal or decreased osteoblasts decreased	Normal	Normal or low	Normal	
Paget's disease	Bones enlarged no polyuria stone infrequent	Polyostotic but not generalized bones hypertrophied, e.g. thickened skull	May occasionally be difficult or impossible to differentiate	Normal or slightly high	Normal or slightly high	Very high	Runs in families predilection for weight bearing bones seldom seen under 40 arteriosclerosis +++
Osteomalacia	No bone tumor polyuria or stones	No tumors or stones bending deformities +++	Osteoid tissue +++ osteoblasts ++ osteoclasts decreased	Normal or low	Low	High	Practically absent in this country except with fatty diarrhea

of the lesions and the presence of normal bone somewhere in the body, especially the small bones of the hands. The involved bones show in most instances a characteristic enlargement (hyperostosis). Thus, the skull is usually thick as well as giving a moth-eaten appearance as compared with the thin moth-eaten appearance in osteitis fibrosa cystica. Aside from the skull, the weight-bearing bones are the ones most involved, e.g., the sacrum. This distribution is not the case in osteitis fibrosa cystica. There is a coarse pattern, difficult to describe, to the trabeculation of the affected bones, which in itself is almost pathognomonic of Paget's disease and contrasts with the sparse irregular trabeculae of osteitis fibrosa cystica. Kidney stones occur, but less often. The serum calcium is normal or only slightly elevated (11 mg), the serum phosphorus is normal or slightly elevated tending to parallel the calcium curve the plasma phosphatase given a

was that of hyperparathyroidism, a kidney stone was present, and a parathyroid tumor was removed. A case that we saw at the Boston City Hospital was almost identical. M. W., a Jewish woman, aged 45, married, complained of bone pain of eight months duration. Roentgenograms showed lesions confined to the pelvis, lower lumbar vertebrae and occiput characteristic of Paget's disease. The serum calcium was 13.2 mg, the serum phosphorus was 2.2 mg, and the plasma phosphatase was very high. A parathyroid tumor was removed by Dr. I. J. Walker. Patient 1 had a thickened mottled skull by roentgen examination typical of Paget's disease, although the rest of the roentgenograms were typical of osteitis fibrosa cystica. Two cases from the literature²⁰ of undoubted hyperparathyroidism have likewise presented such marked thickening of the skull that they led to the clinical diagnosis of Paget's disease. These

observations may be explained by coincidence. The following alternative hypothesis, however, is suggested.

Hyperparathyroidism with its generalized stimulus to osteoclastic activity may enhance the localized unknown factor stimulating osteoclastic activity in Paget's disease. Thus, if the unknown factor causing Paget's disease is present in a patient in a subthreshold amount, a superimposed hyperparathyroidism may make the underlying disease become manifest.

From a practical point of view, we believe that all patients with roentgen evidence of Paget's disease should have their blood chemistry tested in the hope of finding a complicating hyperparathyroidism. In a series of more than thirty cases of Paget's disease so examined in this clinic, however, we have failed to uncover a single one complicated by hyperparathyroidism, aside from case 8, which was first diagnosed at the Huntington Hospital.

Osteomalacia—In this country it is necessary to define what one means by "osteomalacia" (adult rickets) because the term is often used very loosely. It is a condition in which bone tissue shows a definite pathologic abnormality, namely, a failure of calcium deposition in the osteoid "tissue" with resulting widened osteoid seams. The disease is practically nonexistent in this country except in association with fatty diarrhea and resulting lack of absorption of the fat-soluble vitamin D. The bones bend rather than fracture. The serum phosphorus is low. The serum calcium is low or normal. The plasma phosphatase is high. Such patients show a rapid therapeutic response to vitamin D and an adequate diet in contrast to hyperparathyroidism. A biopsy of the bone, if decalcified in such a way as to show the osteoid "tissue," is pathognomonic.

"Solitary" Cysts—A single cyst pathologically indistinguishable from the cysts occurring with hyperparathyroidism is relatively common. This condition is localized. It is to be differentiated from hyperparathyroidism, therefore, by the demonstration of a normal skeleton elsewhere and by the finding of a normal serum calcium, a normal serum phosphorus and a normal plasma phosphatase.

Not infrequently such "solitary" cysts occur in more than one bone, hence the quotation marks. Such cases with multiple "solitary" cysts will, of course, more strongly suggest von Recklinghausen's disease. The following case is interesting in this respect.

N W, a woman aged 23, entered the hospital because of trouble with her right leg, which was first fractured at the age of 8. She had had seven subsequent fractures. She had not had polyuria. The leg was markedly shortened and deformed. Tumefactions of multiple bones could be felt which, by x-rays, were found to be cysts. These were present in the right tibia, right fibula, right femur, right ilium, several ribs, both humeri and the occipital bone. The bones not involved were perfectly normal. The lamina dura was present in the roentgenograms of the teeth. The serum calcium was 9.4 mg, the serum phosphorus 3.2 mg, and the plasma phosphatase 4.1 units. We considered this to be a case of multiple solitary cysts. The possibility that the patient had had a hyperparathyroidism sometime in the past which had spontaneously disappeared cannot be ruled out. Thus a patient with von Recklinghausen's disease several years after operation might show just such a picture.

Solitary Benign Giant Cell Tumor—A benign giant cell tumor may be a completely localized condition or part of an underlying hyperparathyroidism. If the former, the remaining skeleton and the blood values will all be normal.

Osteogenesis Imperfecta (fragilitas ossium)—Osteogenesis imperfecta has thus much in common with hyperparathyroidism it is a generalized bone disease with multiple fractures. It is, on the other hand, hereditary and apt to be associated with blue sclerae and deafness. The pathologic change in the bone consists in a depression of bone formation coupled with normal bone absorption. A biopsy would show therefore, no increase in osteoclasts and no fibrosis. If anything, the osteoblasts and osteoid "tissue" would be decreased. The serum calcium and serum phosphorus are within normal limits. The plasma phosphatase is not elevated, or only slightly so.

Multiple Myeloma—The roentgenograms in this condition may very closely resemble those in hyperparathyroidism. A woman aged 50, showed increased radiability of the entire spine with typical "fish" vertebrae. The diagnosis of myeloma was not made until autopsy. Another patient, E A M, had numerous punctate irregular areas of diminished density in the skull, similar areas in both femurs, fine mottling of all the bones of the pelvis, and a large area of bone destruction in the wing of the ilium giving an appearance similar to a giant cell tumor. The diagnosis was made by biopsy in this case.

Hypercalcemia has been reported in myeloma, although neither of these cases showed it. Hypophosphatemia is not, however, associated consistently with the hypercalcemia. The plasma phosphatase level on E A M was 1 unit, a low normal. Secondary renal changes also develop in multiple myeloma similar to those in hyperparathyroidism.²¹ Thus the biopsy, the lack of hypophosphatemia and perhaps a normal phosphatase level are the deciding points. Bence-Jones proteinuria, if present, would be strong evidence in favor of myeloma, as this has not been reported as far as we know in hyperparathyroidism.

Metastatic Malignancy—This condition (of the prostate, breasts, bronchus, thyroid and hypernephroma) should seldom cause difficulty. Metastases seldom occur below the knees or below the elbows. The involved bone remains normal. Hypercalcemia may develop but not hypophosphatemia. In the case of a metastatic malignant growth of the breast suggesting hyperparathyroidism, reported by Mason and Warren, the serum calcium was 17.3 mg and the serum phosphorus 4.1 mg.

Basophilic Adenoma of Pituitary (Cushing's disease)—Osteoporosis has been one of the features of the syndrome recently described by Cushing, associated with basophilic tumors of the anterior pituitary. It has not yet been definitely decided whether or not a secondary hyperparathyroidism is present in such cases due to a hyperplasia of the parathyroid glands. In one of Cushing's cases²² the serum calcium was normal (9.8 mg), the serum phosphorus was low (2.7 mg), and there was a high calcium excretion in the urine. The obesity, hirsutism, amenorrhea and hypertension in Cushing's syndrome are not features of simple hyperparathyroidism. Schmorl²⁴ and Molneus²⁵ reported an interesting case in which a woman suffered from Cushing's disease plus von Recklinghausen's dis-

case and showed at autopsy both a basophilic tumor of the pituitary and a tumor of the parathyroids. The remaining parathyroids were likewise hyperplastic, suggesting that the tumor was the result of an underlying hyperplasia—that, therefore, the von Recklinghausen's disease was a late manifestation of Cushing's disease in this case.

Other conditions in which the roentgenogram might suggest hyperparathyroidism are radium poisoning, erythroblastic anemia (Cooley's anemia) and the lipid dystrophies. With the roentgenogram the similarity ends, however, and they should offer no difficulty in diagnosis.

SUMMARY

In the clinical aspects of seventeen cases of proved hyperparathyroidism, emphasis has been laid on the different forms which the disease may take, the pathologic changes and pathologic physiology, the signs and symptoms, the laboratory diagnosis, the roentgen diagnosis, the treatment, and the differential diagnosis. We wish to stress the point that, whereas the disease can hardly be called common, it must very frequently be considered when any of a multiplicity of symptoms is present. Failure to make the diagnosis is regrettable in that therapy for it is highly successful.

STAPHYLOCOCCUS TOXOID IN THE TREATMENT OF PUSTULAR DERMATOSES

DANIEL J. KINDEL, M.D.
CINCINNATI

AND

MAURICE J. COSTELLO, M.D.
NEW YORK

Favorable results have recently been reported with the use of staphylococcus toxoid in the treatment of certain pyogenic infections of the skin. Dolman¹ has brought down to date the present knowledge of the subject and has reported some interesting results of his own work. He prepared his own toxoid, standardized it on animals and determined the antibody (or immunologic) titer of the patients' blood during the course of treatment. Twenty-eight patients were treated, suffering from boils, pustular acne, severe pustular dermatitis, eczematoid recurrent infections and other staphylococcic infections. Apparent cure of the infection in each case occurred soon after treatment was begun, when an average total dose of 2 cc was given subcutaneously in eight doses.

In view of several favorable reports, and also because commercial preparations of toxoid were soon to be put on the market, it was decided to make a study of the clinical effects of subcutaneous injections of staphylococcus toxoid in a series of pustular dermatoses. Our investigations were carried out in the outpatient department of Bellevue Hospital.

PREPARATION OF TOXOID AND TECHNIC OF TREATMENT

In the manufacture of the commercial preparation of staphylococcus toxoid that we investigated, the so-called Burky strain of staphylococcus was used because it produces a much more potent necrotizing toxin than any

other strain that was tried. All cultures, broth or agar, were grown under 20 per cent carbon dioxide tension, and dilutions of the toxoid were made in 0.2 per cent peptone. One necrotizing unit of toxin is defined as that amount which will induce in the skin of susceptible rabbits an area of erythema at least 10 by 10 mm with a necrotic center. All toxin filtrates were detoxified with a diluted solution of formaldehyde U. S. P. (0.3 per cent) and standardized on the skin of susceptible rabbits. Three preparations of toxoid were used in this study having values of 200, 400 and 800 units per cubic centimeter, respectively. In beginning this series of cases a 1:10 dilution of the 800 unit preparation was used to determine the severity of the local reactions. After the first few cases were treated this was discontinued because of the mildness or absence of reactions. Subsequently our patients received doses of undiluted toxoid from the outset.

Injections were given on the average of once a week. The dosage was increased as rapidly as possible, its size being determined by the amount of the previous reaction. In some instances the final single dose was as high as 1,200 units. No other treatment of any kind was given. Individual records were kept of each patient, and progress was charted weekly. Seventy-five patients were treated, only forty-two of whom received a total dose of more than 2 cc of undiluted toxoid. The remaining patients failed to return for more than two or three treatments.

The patients were divided into two groups, one of us working with males, the other with females, the two groups being carried along independently. From time to time other members of the staff kindly observed our results.

REACTIONS

Reactions consisted mostly of local manifestations at the site of injection. Many cases showed an area of redness varying from 3 to 10 cm in diameter accompanied by induration and increase in local heat, with some tenderness persisting for a period of forty-eight hours. As the number of injections and the amount of toxoid were increased, the reactions showed a tendency to disappear. In three female patients systemic reactions consisting of malaise, headache and temperature elevation persisted for two or three days after the injection, and in one instance the patient was confined to bed. No focal reactions were noted. Practically no reactions were noticed with the diluted toxoid.

CLINICAL RESULTS

In our series of forty-two cases there were twenty-eight of acne vulgaris, six of furunculosis and eight of sycosis vulgaris. Thirty-five patients had received previous local treatment of one kind or another from various sources. One had taken bromides and five gave a history of ingestion of iodides in the form of iodized salt. Sixteen had used yeast with no improvement and five of these stated that yeast had made the condition worse. One patient developed a series of furuncles after taking three cakes daily for six weeks. Another took yeast daily for two months the eruption becoming worse.

Acne Vulgaris.—Of the twenty-eight acne cases twenty-two were of the pustular and six of the papular varieties. Twelve were severe, eleven moderately severe and five mild. The average number of treatments was 9.4 and the average total dosage of toxoid was 6.11 cc. The smallest total dosage was 2 cc given in four weeks and the largest was 12 cc over a period of fifteen weeks.

From the Department of Dermatology and Syphilology, Bellevue Hospital, service of Dr. Howard Fox.
¹ Dolman, C. E., Treatment of Localized Staphylococcic Infections with Staphylococcus Toxoid. J. A. M. A. 100: 1007 (April 1) 1933.

At the end of treatment the twenty-two cases in the pustular group showed three slightly improved, eleven unimproved and eight worse. Of the papular group two were improved, one was unimproved and six were worse after treatment. In one of the papular cases the iodides were stopped at the beginning of treatment with subsequent disappearance of the eruption. In one patient of the pustular group who had received 12 cc

Summary of Cases Treated with Staphylococcus Toxoid

	Number of Cases	Severity			Average Dosage		Result		
		Mild	Moderate	Severe	Total Dose Cc	No. of Doses	Improved	Unimproved	Worse
Acne vulgaris (pustular type)	22	4	6	12	6.11	9.4	3	11	8
Acne vulgaris (papular type)	6	1	5		6.11	9.4	2	1	3
Sycosis vulgaris	8	2	3	3	5.0	9.6		4	4
Furunculosis	6	2	3	1	5.0	5.0	3		
Total	42	10	14	18	6.0	9.2	8	19	15

of toxoid in fifteen doses a large furuncle developed on each forearm after the last injection.

Sycosis Vulgaris—Eight patients with sycosis vulgaris, of from one to nine years' duration, all of whom had been previously treated, were given an average total dosage of 8 cc in an average of 9.6 treatments. One patient received 15.5 cc in fourteen doses, or more than 1 cc to a dose. As in the acne group, in one of these patients a furuncle of the neck developed following completion of treatment. At the conclusion of treatment all these patients were unimproved or worse.

Furunculosis—Six patients with furunculosis were given an average of eight treatments, the average total dose of toxoid being 5.5 cc. Three patients had either a single furuncle or a single "crop," in no case lasting more than four weeks. These all recovered or improved rapidly. The remaining three patients, who had had recurrent crops over periods of from two months to two years, showed no improvement. Although these three cases cleared up rapidly, attention is again called to the fact that such infections are inclined to be self limited.

SUMMARY AND CONCLUSIONS

1 Forty-two patients with pustular dermatoses including twenty-eight cases of acne vulgaris, eight of sycosis vulgaris and six of furunculosis were treated with staphylococcus toxoid.

2 No patient received less than 2 cc total dosage, the maximum being 15.5 cc, the average was 6.5 cc per case.

3 Of the forty-two cases, eight were slightly improved and thirty-four were unimproved or worse at the end of treatment.

4 Furuncles developed in two cases after large doses of toxoid had been administered.

5 While this series of cases is small, the results appeared to be so definitely unsatisfactory that continuation of this method of treatment seemed unwarranted. Caution should be exercised in becoming overenthusiastic about the value of staphylococcus toxoid until further reports confirm or deny our observations.

DEVELOPMENT OF TETANUS ANTITOXIN FOLLOWING ADMINISTRATION OF TETANUS TOXOID

P. A. T. SNEATH, MD, DPH
TORONTO, ONT.

This communication records the development of tetanus antitoxin in twenty-nine persons following the administration of tetanus formaldehyde toxoid. It will be appreciated that the number submitting to immunization in any one laboratory is much more limited than is the case with diphtheria toxoid, so that an adequate evaluation of tetanus toxoid can be made only by the combined experience from many places.

The twenty-nine individuals were adults, two of whom (subjects 5 and 17 in the table) had had a primary stimulus of tetanus toxoid some years previously. The blood of each was tested for tetanus antitoxin before the toxoid was given. Although the testing was carried down to a level of 0.001 unit, only subject 17 who had had a previous stimulus, showed any antitoxin, 0.004 unit, no trace of antitoxin being evident in the other serums.

Two lots of toxoid were used. One, given to patients 1 to 16, was obtained through the kindness of G. Ramon of the Pasteur Institute, Paris, while that given to patients 17 to 29 was prepared in the Connaught Laboratories. For the guinea-pig, the minimal lethal dose of the toxin from which the latter was prepared was 0.00005 cc, solution of formaldehyde to 0.3 per cent was added and the mixture incubated at 37°C until 5 cc, injected subcutaneously in guinea-pigs, failed to produce any signs of tetanus. This state was reached, for the lot used in this experiment, in a period of six months. The absence of toxicity as well as the ability to stimulate antitoxin production was firmly established by further tests on guinea-pigs and rabbits.

From the Connaught Laboratories, University of Toronto

and sterility was shown by anaerobic and aerobic cultures before the material was released for trial on human subjects

The toxoid was given in three doses of 10, 15 and 15 cc with an interval of one month between the first and second doses, and two weeks between the second and third. Slight local reactions were produced in some instances, showing redness and swelling within the first twenty-four hours and disappearing rapidly. None of the reactions were of a degree to give rise to any concern. Blood serum taken one month after the first dose showed the merest traces of antitoxin in four only, while that of subject 17, who had a previous stimulus and a measurable amount of residual antitoxin, showed 0.1 unit per cubic centimeter. Blood was drawn at intervals thereafter, two weeks after the second dose, one month after the third dose, and from five to seven months after the third dose. The results of the titrations of the serums are shown in the table.

Examination of the table shows that in twenty-eight of the twenty-nine persons given tetanus toxoid demonstrable tetanus antitoxin developed in twenty (including subject 17) to a titer of 0.1 unit or more per cubic centimeter, in six to a titer of 0.01 or $>0.01 <0.1$ units, in one to a titer of 0.003 unit and in one to $>0.001 <0.1$ unit per cubic centimeter. When it is realized that 0.001 unit neutralizes at least 1 minimal lethal dose, and 0.1 unit at least 100 minimal lethal doses, the antitoxin production appears very significant.

The blood taken from five to seven months after the administration of toxoid showed in general a reduction in the antitoxin level but twenty-seven of the twenty-eight still showed antitoxin, thirteen to a level of 0.1 unit or more, twelve to a level of 0.01 unit or $>0.01 <0.1$, one to a level of 0.003 unit, and one to a level of 0.001 unit. It is possible that a different testing method might have demonstrated antitoxin present to a lower level than was possible with the method used, the principle of which was the preservation of guinea-pigs against a lethal dose of the toxin or multiples thereof. The fact, however, that from five to seven months after receiving tetanus toxoid twenty-five of twenty-nine persons showed the very considerable antitoxin titer of 0.01 unit or more per cubic centimeter—capable of neutralizing ten or more minimal lethal doses—while two others showed antitoxin to a lower titer is striking evidence of the efficacy of tetanus toxoid.

There is more than a suggestion in cases 2, 6, 12, 23 and 24 that there was a late increase in antitoxin several months after the last dose. While testing for differences in such antitoxin titers is subject to some errors which must be considered in interpreting these apparent increases, a similar observation of late increase in tetanus antitoxin titer has been made by Ramon¹ and by Lincoln and Greenwald.²

In spite of the small number involved the evidence is fairly definite that the Pasteur Institute toxoid was a superior antigen to that prepared in this laboratory. Not only was the response to the second injection much more marked in those receiving the former but their average level of antitoxin—one month and from five to seven months after the last dose—was much higher. The reason for this difference is not apparent at present.

There is evident, too, the marked variation in the individual response to tetanus toxoid. Thus some

showed as much as 0.5 unit of antitoxin, and one who had received a previous stimulus produced even more, while the majority had at least 0.1 unit. On the other hand, several were found to have much less than 0.1 unit and in the case of subject 26 no antitoxin was demonstrable. Patients 26 and 5, the latter of whom, in spite of a previous stimulus, reached a titer of only 0.001 unit, are examples of refractoriness to immunization such as has been noted previously by Ramon and by Lincoln and Greenwald.

SUMMARY AND CONCLUSIONS

Of twenty-nine persons given three doses of tetanus toxoid, significant amounts of antitoxin developed in twenty-eight, a titer of at least 0.1 unit per cubic centimeter of serum being reached in the majority, or twenty. From five to seven months after the last dose there was, in general, a reduction in the antitoxin level but twenty-seven still showed demonstrable antitoxin, the majority, twenty-five, showing 0.01 unit or more.

This is further evidence that active immunization with tetanus toxoid might be adopted advantageously by certain groups in whom the hazard of tetanus is greater than in the general population.

"HEAVY WATER" AND TUMOR GROWTH

WILLIAM H. WOGLOM, M.D.

AND

LAWRENCE A. WEBER, Ph.D.

NEW YORK

Pursuant to a suggestion by Prof. Harold C. Urey, the effect of "heavy water" on tumor growth has been investigated. This liquid consists of water in which ordinary hydrogen, of mass 1, has been replaced by its isotope, deuterium ("heavy hydrogen"), of mass 2.¹ When replacement is complete, the substance is no longer water but deuterium oxide, quite another material with specific gravity, vapor pressure, and freezing and boiling points differing from those of water.

High concentrations, such as have been shown detrimental to lower forms of animal life and to seeds, could not be employed in the projected experiment, however, on account of their cost, and it was necessary to be content with a preparation in which somewhat less than 0.5 per cent (from 0.40 to 0.42 per cent, according to determinations made by one of us) of the hydrogen was deuterium. Still, as ordinary water has but one part in 30,000 of deuterium, and the sample employed held one part in 250, mice to which it was administered would receive about 120 times their usual intake of "heavy hydrogen," an increment that might conceivably have some effect.

A group of sixty mice averaging 18 Gm in weight were started on a dry diet (dog biscuit), Nov. 15, 1933. Three days later, as they were losing weight rapidly and a few had died, they were allowed a little turnip over the week end. The dry diet was resumed November 21 and continued thereafter throughout the entire experiment. November 27, when the mice had suffered an average loss of 3 Gm each in weight and it was thought that some dehydration must have

occurred, daily subcutaneous injections of 1 cc of physiologic solution of sodium chloride made from the "heavy water" to each of twenty-four animals were begun, while a control group of similar size received ordinary physiologic solution of sodium chloride in the same way

It was anticipated that these injections would restore the original weights, but as this did not happen it is evident that some of the loss mentioned must have been due to causes other than the deprivation of water, perhaps less food was consumed

The "heavy water," as purchased, contained certain impurities in the form of rather stable organic compounds, which were removed by refluxing for four hours with slightly acid permanganate and subsequent fractional distillations from both acid and alkaline permanganate

December 5, one dozen "heavy water" mice and an equal number of controls were inoculated with mouse sarcoma 180, a tumor that takes in 100 per cent and almost never recedes. Because such a vigorous neoplasm might override small effects that would come to light with one more delicately balanced between growth and regression, another dozen "heavy water" mice with their controls, were inoculated with carcinoma 63 which takes in some 75 per cent of cases and disappears spontaneously in a fair number

The injections were continued, with the exception of Sundays and an intervening holiday, until December 18, in the case of sarcoma 180, when seventeen treatments had been given, and until December 30 in the case of carcinoma 63, when twenty-seven had been administered, the experiment having been terminated in both instances by ulceration of the larger tumors. Not the slightest effect on either tumor or host was observed in the mice to which "heavy water" had been given

In order to be certain that the deuterium had been absorbed by the mice and by their tumors the proportion of deuterium to normal hydrogen in the water that

tive index was measured. Check determinations were obtained by repeating the entire process on each sample. In the case of the mice themselves, enough water was available for a preliminary purification by prolonged refluxing with potassium permanganate made acid with phosphorus pentoxide, thus permitting a more rapid distillation through the combustion tube. The results were as given in the accompanying table.

Thus tumor and normal tissues were equally able to take up deuterium

Also seven intravenous injections were given to each of twelve mice bearing carcinoma 63 and five intra peritoneal treatments to three mice with the same tumor. Here the injections were begun one week after implantation of the neoplasm, and again there was no discoverable difference between the "heavy water" mice and their controls

The analyses of the "heavy water" were performed in the laboratory of Dr G M Murphy of the department of chemistry

CONCLUSION

Deuterium, in the amounts that it was possible to administer as "heavy water" had no demonstrable effect on the growth of mouse sarcoma 180 or mouse carcinoma 63

MONILIASIS OF THE SKIN IN DIABETES

E F TRAUT MD
CLEVELAND WHITE MD
AND
R B HEMPHILL MD
CHICAGO

According to Jacobson¹ Langenbeck in 1839 was the first to describe the relation of yeastlike fungi to human disease. They were found in the lesions of thrush in the mouth. Cutaneous moniliasis is common in many classes of patients.

Robin,² in 1853, recognized a variety of yeast as the cause of thrush. Since then, Castellani³ and Stovall⁴ have considerably enriched the literature with reports of fungous diseases in human beings. Clarity and simplification of classification of the yeastlike fungi are due to Stovall and his associates. Stovall identified the yeastlike fungi with the genus *Monilia*. He divides *Monilia* into three species. Species I, represented by *Monilia parapsilosis*, is nonpathogenic, species II is represented by *M. albicans*, and species III by *M. candida*. Both species II and species III have been repeatedly isolated from human vaginitis and thrush.

In textbooks and in the periodical literature on diabetes there are repeated references to the seriousness of pyogenic infections complicating diabetes, with little or no mention of fungous infections excepting that type referred to as genital pruritus or vulvovaginitis.

From the Departments of Medicine and Dermatology, West Suburban Hospital and Cook County Hospital.
The expense of the cultures was defrayed by Therapeutic Grant 143 of the American Medical Association.

Results of Deuterium Injections

Sample	Deuterium Content (Percentage of Total Hydrogen)
1. Water from mice inoculated with mouse sarcoma 180	0.28 ± 0.01
2. Water from mice inoculated with mouse carcinoma 63	0.28 ± 0.01
3. Water from carcinoma 63	0.29 ± 0.01

these contained was determined by measuring its refractive index. Only carcinoma 63 furnished enough tissue for this determination, in which, of course, none but unulcerated tumors were employed. The mice, after their tumors had been removed, were minced and the water then distilled from the tissues in vacuo at 70 C and condensed in a trap surrounded by a solid carbon dioxide-alcohol mixture. The carcinoma was similarly treated. The water so obtained was purified by distilling it very slowly in a stream of dried oxygen through a tube 45 cm long filled with ceric oxide deposited on granular pumice and copper oxide wire and heated to 700 C into a trap surrounded by a carbon dioxide-alcohol mixture. The distillation temperature was kept below 60 C, so that the proportion of water vapor to oxygen was not high enough to interfere with the complete combustion of the impurities in the water. Silver nitrate crystals and solid potassium hydroxide were added to the distillate, which was then redistilled in an all glass (Pyrex) still directly into the cell of the Zeiss interferometer with which the refrac-

The most recent and pretentious work on fungous diseases⁵ refers only cursorily to diabetes as a predisposing factor. Greenwood and Rockwood⁶ found fungous infections of the skin in about 70 per cent of diabetic patients. All the infected patients had the fungus on the feet. Wise and Sulzberger⁷ say that the skin diseases due to *Ordiomyces* (yeastlike fungi) in diabetes have not received the attention in the literature that they deserve both on practical and on theoretical grounds. Recently we have observed two cases of fungous infections (*Monilia*) in males involving other than the genital region. One patient was treated with all the known and accepted fungicides, followed by diabetic management. The second case received only diabetic management.

In 1921 Kumer⁸ found chronic paronychia constantly associated with yeastlike organisms. Kingery and Thienes⁹ first succeeded in experimentally inoculating these organisms from the skin of orange pickers. Hopkins¹⁰ and Kumer found these yeastlike organisms in a diabetic patient with pruritus vulvae. They identified the organisms as *Monilia*. Hall¹¹ refers to the pathologic terrain necessary for infestation by *Monilia*. This is afforded by diabetes.

REPORT OF CASES

CASE 1—E. B., a white man, aged 24, seen by one of us in June 1927, had known of his glycosuria for two weeks but for six months had had polyuria, polydipsia and a loss of 10 pounds (4.5 Kg). He had had eczema as a child and many severe attacks of urticaria in late years. There was no family history of diabetes. He was well nourished and tawny. The breath was foul but no acetone was detected. There was no dyspnea. The teeth were in good condition, the tonsils had been removed. The eyes reacted normally. The chest and abdomen were normal. The blood contained 170 mg of dextrose per hundred cubic centimeters. The urine gave maximum tests for sugar, acetone and diacetic acid. When he left the hospital his condition was controlled on a diet furnishing 161 Gm of dextrose. He received 70 units of insulin daily. His general condition had much improved.

Between that time and July 1931 he had considerable difficulty in keeping the urine sugar free without hypoglycemic reactions. In July 1931 he was treated for an infection of the dorsum of the left foot. It was then noted that the pulsations in the dorsalis pedis arteries were weak. The infection cleared up. He was next seen Feb. 12, 1933, with a pronounced superficial mycotic dermatitis having a well defined oozing area on the plantar surface of the right large toe. It had been present for four months and was exaggerated (patient's statement) with the usual 'ringworm' remedies. There was marked swelling of the lymph glands in both inguinal regions. He had been thoroughly instructed in the modern home care of diabetes and presumably was sugar free. Scrapings taken for microscopic potassium hydroxide examination showed the hyphae and spores of *Monilia*—*Monilia albicans* grew on Sabouraud's isolation culture mediums. Treatment both with organic dyes and with the usual fungicidal preparations produced a superimposed dermatitis. The fungous infection was unabated.

The diabetes was found to be out of control. In July the patient entered the West Suburban Hospital. The usual dietetic measures and a sufficient dose of insulin cleared up the glycosuria. The feet were simply kept exposed and external medication was discontinued.

He left the hospital in a much improved condition and since then he has progressed satisfactorily on management consisting

of controlling the diabetes and leaving his feet and legs exposed to the air as much as possible. In order to accomplish this he goes stockingless and wears sandals of the type known as "beach sandals." When last seen the diabetes was well controlled and his skin had a normal appearance and texture.

CASE 2—E. J., a white man, aged 59, who entered the Cook County Hospital, Aug. 3, 1933, had had an ulcer of the right foot for six months. Vesicles and bullae on both hands for two days and swellings below the eyes one day. He has had diabetes since 1928 and has been on an unweighed diet and insulin since. In 1930 the great toe of the right foot was amputated because of diabetic gangrene. Since January 1933 he has noticed an ulcer under the head of the right fifth metatarsal. It has become larger, especially during the past month (July). Two days before admission he first noticed numerous small vesicles over the dorsum of both hands extending along the dorsum, particularly between the fingers. One day before admission he noticed a swelling under both eyes. The hands and face itched considerably. He gave no history of illness other than diabetes. His family history was essentially normal. The blood pressure was 170 systolic, 94 diastolic. The brachial arteries were sclerotic. The inguinal glands bilaterally were palpable. It is now known that mycotic adenopathy can occur.¹⁰ There were no other masses or areas of tenderness.

On the right foot was an ulcer under the head of the fifth metatarsal. This area was tender to touch. The skin over both feet was shiny and red. There was no difference in temperature. The popliteal and dorsalis pedis arteries of both feet did not pulsate. There were numerous small vesicles over the dorsal surfaces of both hands and particularly between the fingers. Some of the lesions were crusting. One small area of a scaling, red, shiny eruption was present on the back.

To the dermatologist the lesions on the face appeared to be a dermatitis venenata that was receding. The lesions of the fingers and hands were considered an eczematoid fungous dermatitis. On microscopic examination of the lesions on the hand, *Monilia* was shown to be the causative agent.

The blood sugar on admission was 240 mg per hundred cubic centimeters, and the urine was positive for sugar.

The patient was put on dietary management and given 10 units of insulin daily. Local treatment consisted only of a soothing ointment to the face. He left the hospital, August 15, with the lesion of the hands and face definitely cleared up, although the ulcer on the foot had broken open and was draining.

COMMENT

The cases presented are both cases of diabetes complicated by infection with *Monilia*. The first patient received the usual fungicides without improvement, instead, the condition became much aggravated. In the first case the allergic constitution previously manifested by urticaria and the precocious endarteritis probably contributed to the severity of the fungous disease.¹¹ The second older, patient also had a predisposing obliterating endarteritis. This patient showed the "id" reaction to the fungous toxin about the eyebrows. He had received no treatment prior to admission to the hospital. Both cases responded rapidly to competent diabetic management without local fungicidal medication.

It has been presumed that the glycosuria irritated chemically the tissues with which it came in contact. This was the prevailing explanation for the pruritus and the vulvovaginitis of the diabetic patient. In our observations, such local inflammations have been the result of local infection with fungi.

Competent diabetic management seemed to be the deciding factor in the treatment of *Monilia* infection of the skin in both instances. To us, this is the all

¹¹ Personal communication from Dr. Geza de Takats. It is generally known that cases of poor circulation, whether due to phlebitis or to an arterial process, frequently have a superimposed fungous infection. This is especially true of older diabetic patients in whom fungous infection may be the starting point of gangrene.

important therapeutic maneuver in the treatment of fungous infection in diabetes

P Perazzi¹² reports a case of *Monilia vaginitis* which he treated with diet and insulin. He noted marked improvement without the use of any local therapy. Perazzi is of the opinion that the dextrose in the urine is a factor in the production of *Monilia vaginitis*.

Plass, Hesselstine and Borts¹³ and Hesselstine¹⁴ feel that the dextrose in the urine plays no part in the fungous infection of the female genitalia.

Plass, Hesselstine and Borts further recall that Sabouraud's medium, which is the medium of choice for fungous cultures, is adjusted to a p_H of 5.5. Whether or not the skin p_H in diabetes approaches this level, and thereby contributes to the extensive growth and stubbornness of the fungous infections, warrants further investigation.

CONCLUSIONS

1 In neither of two cases of superficial fungous infections of the skin (moniliasis) in diabetes could the sugar in the urine have been the direct cause except as it indicated the presence of uncontrolled diabetes.

2 One case did not respond to ordinary fungicides but did respond to diabetic control. The other case responded immediately to diabetic control.

3 It is felt that the control of the diabetes is all important in the treatment of these complications.

THE EFFECT OF INTRAVENOUS HYDROCHLORIC ACID IN NARCOSIS

EXPERIMENTAL OBSERVATIONS

PHILIP SHAMBAUGH, M.D.

AND

ROBERT BOGGS, M.D.

BOSTON

Widespread interest has recently been aroused by an enthusiastic report by MacGilvra¹ of the use of intravenous hydrochloric acid as a means of promptly terminating anesthesia both in experimental animals and in man. In the report, successful results are described in terminating ether anesthesia in rabbits, guinea-pigs, rats and monkeys. It was also used successfully in a patient who appeared moribund from the effect of tribrom-ethanol (aveitin) anesthesia. The author suggested that the treatment might be equally efficacious in other forms of anesthesia. In view of the obviously great clinical value which a successful and safe method of terminating narcosis would have, it seemed advisable that this procedure should be immediately subjected to further carefully controlled experimental observations.

In a preliminary report² we described the results of the intravenous injection of varying amounts of tenth normal hydrochloric acid in dogs which had been anesthetized with ether, tribrom-ethanol and pentobarbital sodium (nembutal). In no case were we able to demonstrate the least effect on the rate of recovery. In

spite of these discouraging results, it was felt advisable to continue the observations, using other laboratory animals. Our experiments have now included dogs, guinea-pigs, rabbits, monkeys (*Macacus rhesus*) and

cases in which it was felt that the stimulation incident on the venipuncture might hasten the recovery rate, the control animal was merely pricked with a needle. The rate of recovery from narcosis was determined, as accurately as possible, by noting the time of the return of the wink reflex, voluntary movements of the legs,

attempts to stand, and finally the ability to stand unassisted. The results are shown in the accompanying tables. The time intervals noted were taken from the withdrawal of the anesthetic in the case of the ether and from the point of deep narcosis in the case of tribrom-ethanol and pentobarbital sodium. The hydrochloric acid was injected at the onset of the timing, and when more than one dose was given these followed at varying intervals of from five to thirty minutes.

In the case of ether anesthesia, as is noted in table 1, the recovery rate was quite rapid even without any form of treatment. This was especially true in the rabbits,

* Control

guinea-pigs and baboons so it would necessarily be very difficult to establish the value of any form of therapy in these animals. As far as we could judge however, the acid in no case shortened the recovery period. Two of the rabbits were inadvertently overanesthetized, and in these the injection of the acid within a few seconds of the cessation of respiration was without effect. Pentobarbital sodium (table 2) was selected as representative of the barbiturates and was administered intraperitoneally, in a 3 per cent solution in physiologic solution of sodium chloride. The doses in most cases approximated 30 mg per kilogram. As in the case of ether, we found the acid to be entirely without effect even when given in massive dosage totaling in one case 350 cc. The observations in tribrom-ethanol narcosis (table 3) were likewise completely negative.²

SUMMARY

Observations on guinea-pigs, rabbits, dogs, monkeys and baboons indicate that the intravenous injection of dilute hydrochloric acid is without effect as a means of shortening the recovery period from ether, pentobarbital sodium and tribrom-ethanol narcosis.

² W. deB. MacLider in the course of his extensive investigations in dogs on the effect of intravenous hydrochloric acid on the kidneys observed no change in depth of anesthesia induced by chloroform and morphine (personal communication to the authors).

The pH of the Blood.—The reaction of the blood is normally in the resting man expressed by a pH of 7.4 slightly more alkaline than water. The pH may be raised 0.2 or 0.3 above this level by such a simple physiological means as blowing off carbonic acid in voluntary overbreathing. And it can be lowered as much by the lactic acid produced in the muscles in a short hard sprint. But if the change goes much farther in the alkaline direction the tetany of alkalosis sets in nor can much greater change in the acid direction be tolerated without the symptoms of acid poisoning. The range within which life is continuously possible seems to be the narrow zone between pH 7 and 7.8. When we consider that some molds can grow in 5 per cent sulphuric acid solution it appears that the efficiency of our complicated and delicate organism has been bought at a heavy cost in cellular hardness and adaptability. —Van Slyke D. D. Acidosis and Alkalosis. *Bull. N. Y. Acad. Med.* 10: 103 (March) 1934.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF GONORRHEAL VAGINITIS IN IMMATURE GIRLS

JOSEPH BROWN, M.D., DES MOINES, IOWA

My purpose in this note on the treatment of gonorrheal vaginitis in immature girls is to corroborate the work and observations of Lewis.¹

Gonorrhea in young girls has always been the bugbear of the medical practitioner and seldom is cured short of months of intensive treatment. Because of the delicacy of the structures involved and the lack of cooperation on the part of the young patients, local treatment is difficult. At best, even in older girls, when cooperation is more readily obtained treatment is long and tedious and highly unsatisfactory. Perhaps the reason for this is to be found in the peculiar microscopic changes in the generative tract of the immature girl, so splendidly shown by Schaeffer and Kuhn.²

It has long been known that gonorrhea in the mature female seldom attacks the vaginal wall per se or, if it does it is of short duration. Allen³ demonstrated that estrin, when injected into immature monkeys, caused vast proliferation of the layers of the vaginal mucous membrane, producing almost an adult type of mucous membrane. Lewis utilized this knowledge and brought out the newer treatment of gonorrhea in immature females.

* There were no constitutional reactions, complications or vaginal bleeding.

After reading the report of Lewis I undertook to verify his results in the clinic of gonorrhea in young girls at the Broadlawn (City) General Hospital.⁴ This clinic had shown persistently unsatisfactory results as far as duration of disease and end results were concerned. I had charge of this clinic for several months about five years ago.

Seven patients had been coming two or three times a week for periods varying from months to years. One patient had been coming at regular biweekly periods for the past four and one half years and had taxed the resources of attending men and several crops of interns.

The accompanying table summarizes briefly the seven cases. Theelin exclusively was used in all cases.

I found with Lewis that none of these children had vaginal bleeding as a result of the extra stimulation of the sexual

⁴ By courtesy of Superintendent Dr. Charles Sprague.

apparatus, and none had any constitutional reactions. In only one did I notice any marked turgescence of the labia majora and very slight palpable enlargement of the breasts, and that child was the youngest in the series and had the largest number of injections and the largest total quantity of units of hormone. I also found, with Lewis, that the profuse, purulent vaginal discharge frequently found in this condition disappears almost entirely after the fourth or fifth injection.

In this series no local treatment was used, not even washing of the vulva. Smears of the vagina were taken at least twice weekly during treatment.

We are still watching these youngsters with slides and cultures at varying intervals and to date these have remained negative and there has been no return of clinical manifestations of gonorrhea even several weeks since the last treatment was given. Perhaps the greatest compensation I had for my investigations was the bright and happy smiles of the youngsters as we handed them their notes that would readmit them to the common fellowship of the schoolroom after an absence of months and, in one case years.

I present this brief and necessarily incomplete report on the newer treatment of gonorrhea in immature girls with the use of theelin because there may be many practitioners still struggling with this difficult pediatric and gynecologic problem. This new treatment presents great possibilities for lessening the severity and duration of the disease and may show a way for a rapid clinical and bacteriologic cure of a heretofore distressing malady.

BILATERAL CHYLOTHORAX AND CHYLOPERITONEUM

GEORGE J. HEPPNER, M.D., SAN FRANCISCO

Unilateral chylothorax or chyloperitoneum alone although not frequently found, has been reported several times. To my knowledge there are no cases in the literature in which chyle has been recovered in the three major cavities of the body.

REPORT OF CASE

G. B., a woman aged 19, while riding in the rumble seat of an automobile, May 14, 1933, met with an accident which resulted in a transverse fracture of the left humerus in its middle third. cursory examination showed no other injuries, and a body spica was applied following closed reduction. Roentgenograms revealed excellent position of the fragments. At the end of two and one-half weeks a roentgen recheck showed that the fragments had slipped. A general anesthetic was given and a pin was placed through the olecranon and traction applied. Symptoms of nerve paralysis appeared and accordingly, under a second general anesthetic, an open reduction was performed three weeks following the injury. A silver wire was placed through the fragments. Three weeks later (six weeks after the injury) a roentgenogram showed practically no callus. The patient now started complaining of tightness of the body cast and some shortness of breath. This was attributed to lack of exercise as the patient actually put on 12 pounds (5.4 Kg.) in weight. Two weeks later because of pressure, the body cast was removed. A roentgenogram of the arm showed the alignment to be good and a moderate amount of callus present. When the cast was removed, a moderate amount of abdominal distention was recognized but no fluid wave was obtained. Stupes and enemas failed to take the distention down. One week later (nine weeks after the injury) the patient was confined to bed with what appeared to be symptoms of influenza—slight cough, sore throat, aches and pains in the back and limbs, and an afternoon temperature of 102. Influenza therapy of catharsis, liquids, antipyretics and cough syrup was given without improvement. Three days later a definite fluid wave appeared in the abdomen which during the course of the next week progressed so rapidly that it encroached on the diaphragm. Roentgenograms of the chest revealed a small fluid level of both bases. The heart was pushed up by the diaphragm and at the right of the inferior right border of the heart was a shadow the size of a walnut, at this time unexplained.

Because of the respiratory embarrassment and the increasing distention, an exploratory laparotomy was performed, July 29 (eleven weeks after the injury), at which time a gallon and a half of milky fluid was drained out of the abdomen. The only positive observations in the abdomen were an omentum entirely denuded of fat, and a more or less hard nodular pancreas. Tissue from the pancreas was removed, and the abdomen closed with one large rubber drain inserted. Convalescence was uneventful and primary closure of the wound was obtained in eighteen days. On the eighteenth postoperative day the patient first experienced difficulty in breathing, and investigation showed both bases to be dull. This condition was confirmed by roentgen examination, and thoracentesis on alternate sides of the chest produced fluid, which, on standing, had a layer of red cells at the bottom, a milky second layer, and a third so-called cream layer. In nine days six punctures were done (four left, two right). On the ninth day (after respiratory embarrassment) she was fed back almost a quart of the chyle by mouth, and immediate improvement occurred, so much so that four days later she was allowed to sit up in a wheel chair. Relief was short lived, however, as immediately after the patient sat up the abdomen again became markedly distended, not badly enough, however, to warrant paracentesis for one week, at which time two liters of pure white fluid was obtained pathologically reported as chyle. No relief was obtained following this procedure, so that again the chest was tapped, most of the fluid now being in the right side of the chest, as compared to the left side two weeks before. Five more punctures were made in the next seven days.

The abdomen was again tapped and 300 cc. of air injected. A roentgenogram immediately following showed air below the crus of the diaphragm, both right and left, but there was an area about one inch in diameter on the right side which showed no air. This was interpreted as being a cyst continuous with the walnut sized mass reported on the inferior border of the right side of the heart. Heroic measures were instituted, two transfusions were given, and drainage of the cyst from the posterior chest wall at the level of the tenth, eleventh and twelfth dorsal spine was achieved by Dr. A. L. Brown. The patient died the next day while on the bedpan.

PATHOLOGIC REPORT

There was an interruption in the continuity of the thoracic duct 2.5 cm. above the diaphragm, with some fibrosis about the distal end of the broken area apparently occluding the lumen. The proximal end showed a tiny patent lumen, although there had been some desmoplastic reaction about it. There was chylous fluid in both pleural cavities and the peritoneal cavity, this was much thinner than in the pleural cavity.

Both lungs were collapsed. They weighed 225 Gm. each and showed massive old adhesions about the bases on each side. On the right there was a dense mass of succulent adhesions at least a month old. The liver showed cloudy swelling of the cells, the spleen showed a congested pulp, the pancreas was normal in size but was very hard owing to loss of fat. The suprarenals showed a fresh hemorrhage occupying the medulla and inner cortical zones. The kidneys were normal. The intestine showed an intense edema, vascular congestion and dilatation of the lacteals. The sex organs were normal, except for edema.

The diagnosis was ruptured thoracic duct with chylothorax, chyloperitoneum, fatty infiltration of the liver, fibrinopurulent pleuritis and terminal fatal bilateral suprarenal apoplexy.

COMMENT

This case is unusual in that there was a bilateral chylothorax and chyloperitoneum following trauma.

A new approach as to drainage was attempted, in an endeavor to obtain collateral circulation of the lymph channels, mean while taking undue pressure off the pleural cavity and the diaphragm and abdominal spaces.

Whether or not the operation is of any avail is open to discussion because of the emaciation and inanition resulting from the loss of normal chyle which cannot forever be artificially replaced and may in itself lead to eventual death.

490 Post Street

DIPHThERITIC VULVOVAGINITIS AND DIPHThERIA
OF THE SKIN, MOUTH AND THROAT

ROD H. CANTRELL, M.D., DALLAS, TEXAS

This case of diphtheritic vulvovaginitis and diphtheria of the skin is being reported because of the rarity of its occurrence. The material on the subject in the available American literature is quite limited. Shrewsbury¹ reports a case of cutaneous infection of the thigh with a diphtheroid bacillus, identical with the Klebs-Löffler bacillus in every respect except in toxin production. This lesion healed in three weeks, only after curettage and iodoform dressings. Anderson² describes a case of gangrene of the skin, due to diphtheria. Warren and Sutton³ contribute a fatal case of diphtheria of the skin, superimposed on varicella. Massey and Russell⁴ record a case of diphtheria of the skin which was the cause of an outbreak of diphtheria. Montgomery⁵ mentions a case of diphtheria of the skin about the umbilicus, in which the umbilicus of a baby 7 days old was the site of primary infection.

REPORT OF CASE

P. C., a white woman, aged 28, admitted to the urologic service of the Dallas City-County Hospital Sept. 1, 1933, complained of ulceration of the vulva and of the skin under both breasts. The ulceration of the vulva began about six weeks previous to admission, as an irritation of the skin with a foul vaginal discharge. The patient went to a physician, who gave her an ointment and told her that the disorder was due to a nervous condition. Three or four days before she came to the hospital ulcers appeared and the vulva became swollen and extremely sore, causing excruciating pain on voiding and defecating, the ulceration having extended back to the region of the anus and on the buttocks. Two days before the skin under both breasts became ulcerated and was very painful.

The patient was rather obese and anemic. The mouth showed marked pyorrhea. The tongue presented one ulcer on the right side, about 2 cm. from the tip and about 1 cm. in diameter. It was gray, on an indurated base. The right tonsil had a few small gray spots on it, similar to the one on the tongue.

The chest and heart were normal. The breasts were large and pendulous, the skin on the lower surface and on the chest wall beneath was excoriated over an area about 3 inches in diameter. These areas were very tender.

The vulva was greatly swollen and excoriated. This excoriation extended back to the region of the anus and on the buttocks. There was a rather heavy mucoid discharge between the labia but no evidence of a membrane. A very foul odor was present.

The temperature on admission was 102 F, pulse 118. The temperature ranged between 100 and 102 for four days then rose to 104.4 but came back to 100 on the fifth morning and remained about 101 until death on the tenth hospital day. The pulse ranged from 90 to 120 during the entire ten days.

September 2 the blood count revealed red blood cells, 2,700,000, white blood cells, 6,000, polymorphonuclears 72 per cent, small lymphocytes, 24 per cent, large lymphocytes 4 per cent, and hemoglobin, 55 per cent (Sahli). Examination of the urine was negative except for 30 pus cells per low power field. A smear from the vulva revealed many staphylococci, many bacilli of various types and a moderate number of leukocytes. The Wassermann test was negative.

A blood count, September 6, revealed red blood cells, 3,410,000, white blood cells 7,600, polymorphonuclears 68 per cent, small lymphocytes 16 per cent, large lymphocytes, 16 per cent, and hemoglobin 70 per cent. A smear from the throat showed many diphtheria bacilli. A smear from the vulva showed no diphtheria bacilli.

A blood count (Schilling) September 7, revealed red blood cells 3,320,000, white blood cells 6,800, polymorphonuclears

47 per cent, small lymphocytes, 36 per cent, large lymphocytes 12 per cent, hemoglobin, 65 per cent, and single lobed neutrophils, 5 per cent. A vaginal culture yielded many diphtheria bacilli. A throat culture yielded many diphtheria bacilli. Blood cultures were repeatedly negative.

On the sixth hospital day the mucous membrane on the right cheek became sore and was covered with a gray membrane and the face was badly swollen. The swelling increased and the ulceration spread to the lips and then around to the skin of the face, involving an area about 2 cm. in diameter.

As treatment, potassium permanganate, 1:5,000, as an external douche to the vulva, was used three times daily. Lights over the vulva were tried, but the patient complained. Boric acid was then used, which was more soothing. Boric acid was used on the skin of the breasts and sodium perborate was used as a mouth wash.

A transfusion with 400 cc. of blood was given, September 6.

On the sixth hospital day, 20,000 units of diphtheria antitoxin was injected into the muscle and 5,000 units intravenously, 40,000 units daily for the next two days and 20,000 units on the day of death were given intramuscularly, but the patient continued to grow weaker. The total amount of antitoxin given was 125,000 units.

September 9, pneumonia developed, and on the following day the patient died. An autopsy was not done.

This case⁶ is of interest from the standpoint of being primarily a diphtheritic vulvovaginitis, secondarily of the skin, then of the mouth and throat. The leukopenia seen is rather unusual, a moderate leukocytosis is the rule in cases of diphtheria. We thought chiefly of drug eruptions and on September 6 had Dr. A. G. Schoch see her. After questioning the patient closely about the use of drugs and obtaining negative answers to all his questions, he suggested that we get smears and cultures for diphtheria.

EXFOLIATIVE DERMATITIS FOLLOWING INTRA-
VENOUS INJECTION OF COLLOIDAL
SULPHUR WITH RECOVERY

NORMAN TOBIAS, M.D., ST. LOUIS

Primary dermatitis exfoliativa (Hebra) is rare and recovery is unusual. The secondary exfoliative dermatoses (Brocq) usually occur during the treatment of such common skin disorders as psoriasis, seborrheic dermatitis, extensive eczema, lichen planus and lupus erythematosus. This complication may supervene in certain individuals, possibly as a form of allergic response during therapy, which may be local (mercury, chrysarobin, iodoform), internal (quinine) or parenteral (antitoxins, serums, arsenicals, heavy metals).

Colloidal Sulphur (Doak) has been recently advocated for chronic arthritis, neuritis, sciatica, arsenical dermatitis and seborrheic eczema. Each 2 cc. ampule represents 5 mg. of sulphur and injection is made intravenously semiweekly.

REPORT OF CASE

Mrs. E. M., aged 26, seen in January 1933, had a chronic seborrheic dermatitis consisting of large subacutely inflamed patches on the back of the neck, left infraclavicular region, left gluteal region and right thigh. The lesions began to appear six years before and, although various ointments had been applied by as many physicians, no apparent improvement could be ascertained. After sulphur, resorcinol and tar ointments in graduated strengths had failed to influence the lesions, roentgen treatments in fractional weekly doses were given. A diet low in fats and oils was also followed.

Since there was no change for the better in any of the lesions after two months of local treatment the patient was given an intravenous injection of 2 cc. of Colloidal Sulphur (Doak). Twenty-four hours later a severe pompholyx-like eruption developed in both palms, with edema on the dorsal surfaces of both hands. Two days later the face and neck became hyperemic and in a week the entire cutaneous surface was erythematous. Then scaling followed which gradually

⁶ I am indebted to Dr. R. E. Van Duzen for permission to report this case.

Read before the Dallas County Medical Society, Oct. 12, 1933.

² Anderson, J. D. A Case of Gangrene of the Skin Due to Diphtheria. Brit. M. J. 2: 800 (Oct. 31) 1931.
³ Warren, Shields, and Sutton, Lee, Jr. A Case of Diphtheria of the Skin Which Was the Cause of an Outbreak of Diphtheria. J. A. M. A. 84: 1983-1984 (June 27) 1925.
⁴ Massey, Arthur, and Russell, Gladys. A Fatal Case of Diphtheria of the Skin. Brit. M. J. 1: 992-993 (June 19) 1929.
⁵ Montgomery, J. C. Diphtheria of the Umbilicus. Am. J. Dis. Child. 40: 968-973 (Nov.) 1930.

became more marked on the trunk and lower extremities. One month after the onset the nails became dystrophic and loosened. Alopecia of the scalp and eyebrows was almost complete three months after the injection. With hospitalization, forced fluids, soothing lotions and general ultraviolet irradiation the patient made an uneventful but slow recovery, which required eight months. The hair and nails have been replaced and the original lesions of seborrheic dermatitis have disappeared. Whether they will return at some future time is a question.

While the patient was in the hospital, physical examination revealed no gross abnormalities of the internal organs. Blood examination revealed white blood cells 6,900, red blood cells 3,100,000, hemoglobin 60 per cent. Differential count revealed stab cells 7 per cent, segmented cells 63 per cent, neutrophils 70 per cent, eosinophils 3 per cent, mononuclears 6 per cent, lymphocytes 21 per cent. The nonprotein nitrogen was 24 mg. per hundred cubic centimeters, blood sugar 80. The Wassermann and Kahn reactions were negative. The urine showed a trace of albumin and an occasional erythrocyte. Biopsy was not permitted.

CONCLUSIONS

Although thousands of injections of Colloidal Sulphur have been given in this country, no reports of exfoliative dermatitis from its use could be found in the literature. In the reported case intradermal and patch tests might have revealed a possible intolerance or sensitivity.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE
H. A. CARTER, Secretary

PHYSICAL THERAPY COMMITTEES IN STATE AND COUNTY MEDICAL SOCIETIES

AN OUTLINE OF ORGANIZATION AND PLAN OF ACTIVITIES

RICHARD KOVACS, M.D.

NEW YORK

Physical therapy as part of the practice of medicine has made considerable advance in recent years. Systematic instruction in undergraduate and postgraduate schools, critical research in adequately equipped institutions and authoritative information issued periodically by the Council on Physical Therapy are gradually replacing objectionable propagandizing methods employed by commercial concerns. Yet in many parts of the country the profession as a whole does not evaluate properly the possibilities and limitations of physical measures. As a result there occur many errors of commission, such as the overenthusiastic and unwarranted uses of physical therapy procedures, and also errors of omission, for example, the exploitation of valuable measures by irregulars and lay persons instead of by qualified physicians.

Because educational activities by special committees organized in state or county medical societies, have proved most effective, they are a desirable means of familiarizing the general practitioner with sound methods of physical therapy. Committees of such character have been successful in New York, Pennsylvania and California. Their work might well point the way for similar activities in other state or county medical bodies.

ORGANIZATION

The initiative for the organization of physical therapy committees in county or state societies must come from among the local society membership. The appointment of such a special committee could be secured by a motion at any regular business meeting of a medical body. The resolution may stress the desirability of surveying the status of physical therapy within the county or state: (1) its employment (a) by general practitioners (b) by institutions (c) by technicians under some sort of supervision of the organized profession (d) by unlicensed practitioners and other irregulars, (2) the opportunities for education of (a) graduate physicians (b) undergraduate students, (c) nurses and other technicians. To create a larger scope of interest in some states or counties, it may be desirable to include in the scope of the committee's proposed work a similar survey of the status of x-ray and clinical laboratory work.

A physical therapy committee when appointed, should be headed by a physician who is familiar with physical measures and who enjoys the confidence of his medical confreres. Its membership should include physicians interested in general medicine, surgery and orthopedics and as a rule the number should not exceed five or six. A committee appointed by a state society may in turn recommend the appointment of special physical therapy committees in the larger county units and encourage their activity within their own sphere. Likewise, a committee appointed in one of the counties can become instrumental in securing the formation of a committee covering the entire state.

WORKING PLAN

The chief tasks confronting committees on physical therapy are to impress on the rank and file of the medical profession that (1) the rational use of physical measures is part of the practice of medicine, consequently the members of the medical profession must receive adequate postgraduate instruction in physical therapy from competent leaders, and that (2) the practice of physical therapy by unlicensed people and its independent practice by lay technicians should be prevented by medical practice statutes.

An effective method of drawing the interest of the profession to the committee's problems at the onset of activities is the making of a survey of the practice and teaching of physical therapy along the lines already indicated. A suitable questionnaire may be sent to local hospitals, institutions and medical schools.

From hospitals certain information might well be sought for example (a) as to whether or not they possess a physical therapy department or employ any methods coming within the scope of physical therapy, (b) as to what type of equipment is being used and (c) as to whether or not the department is under the direction of a qualified physician. It is a fact that in too many institutions lay technicians have been placed more or less in charge of physical therapy. In some instances this unfortunate situation was brought about by the attitude of certain poorly informed members of the hospital staff, who were satisfied if application of heat, massage and exercise was carried out according to their own or their technician's notion.

It must be realized that a well conducted physical therapy department should be capable of rendering service to all departments of a hospital, not unlike an x-ray department. The best way to insure such service is to place a widely trained physician in charge. One

who will interest his fellow members of the staff in the existing facilities. Leaving a lay technician in charge inevitably leads to the assumption of unwarranted authority, such as the prescribing of treatment and the judging of results. It also deprives patients of the benefits of intelligently supervised physical therapy.

Properly equipped and directed physical therapy departments in hospitals are also of prime importance for the practical instruction of general practitioners as well as of medical students. The committee should offer its help in the organization of new departments if the occasion arises and make available opportunities for the training of physicians who are to be in charge.

Medical schools might well be asked whether the curriculum includes any instruction for graduates or undergraduates and what features this instruction comprises. The lack of properly manned physical therapy departments so far has unfortunately retarded the training of qualified teachers as well as the development of critical research and clinical work comparable to that going on in other departments of medicine.

EDUCATIONAL ACTIVITIES

The main aim of a successful physical therapy committee should be the inauguration of suitable instruction concerning scope and methods of physical therapy. This can be done through single lectures at the stated meetings of the medical body or by special or postgraduate courses arranged for all members of the society, no charge being made. Although the content of the course may be varied to suit the local needs, the following five-lecture postgraduate program has been suggested:

First lecture Heat measures therapeutic effects

Second lecture Massage therapeutic exercise

Third lecture Hydrotherapy Physical therapy in medical conditions

Fourth lecture Ultraviolet radiations Physical therapy in surgical, gynecologic, and other special conditions, low frequency currents and electrodiagnosis

Fifth lecture Inhalation therapy Use of oxygen, carbon dioxide, and so on, in resuscitation, anesthesia and pneumonia

It was found that both single lectures and systematic lecture courses stimulated further interest in the subject, affording an opportunity to spread correct information and to counteract much of the existing misinformation. A five day seminar was held under the auspices of the Committee on Education of the Philadelphia County Medical Society. The entire series of these lectures was published in book form. Again, a one week postgraduate seminar was given under the endorsement of the Los Angeles County Medical Association. All of these lecture courses were combined with clinical demonstrations offered at physical therapy departments in hospitals.

When drawing up an outline for similar courses in other states or counties stress should be laid on the use of simple measures, such as heat massage and therapeutic exercise, suitable for the general practitioner, and too much emphasis on therapy by complicated apparatus should be avoided. If there are no suitable speakers available in the county or state, the Council on Physical Therapy is in position to offer a list of speakers, and it can also name men and institutions competent to give regular postgraduate courses suitable for those who wish more extended instruction.

In addition to these courses of instruction, provision may be made in localities where there are physical

therapy departments under qualified leadership to have these departments open for inspection by interested physicians. Lists of such institutions should be published for the benefit of the local profession from time to time.

Chairmen of the medical boards of hospitals possessing physical therapy departments might well be urged to encourage the presentation of physical therapy cases at staff meetings, in order to stimulate intelligent discussion of the values and limitations of physical measures.

At annual meetings of state societies, papers on physical therapy subjects should be placed on the program, either at general meetings or, when there is enough interest at a special half day session. The latter plan has been carried out in New York State successfully for five consecutive years and it is gratifying to observe the improvement in the type of papers and the level of discussion from year to year.

It is recommended that at scientific meetings where the papers bear relation to physical therapy, comments by an authority on physical therapy should form part of the program.

MISCELLANEOUS ACTIVITIES

Manufacturers of physical therapy and x-ray apparatus or their representatives may be asked to cooperate with the committee's efforts to raise the standards of physical therapy. Those who wish to remain in the good graces of the organized profession might well be advised to pledge themselves not to establish or promote any commercial lecture course, relying only on those which are given under the auspices of the organized medical profession. Leading manufacturers in conference with physical therapy committees have subscribed to the principle that instruction in diagnosis and therapeutics belongs solely to the province of the medical profession. The only instruction that an ethical manufacturer can consistently offer to the profession is on the manipulation and care of some certain type of apparatus.

The maintenance of acceptable standards in compensation work may also receive attention. In some of the larger centers, low grade industrial clinics and unscrupulous physicians have attempted to turn the wholesale use of physical measures into mere sources of revenue. The medical profession must be informed that in traumatic and other cases physical measures are to be employed only (1) after a complete diagnosis has been established, (2) when the existing pathologic or functional changes serve as an indication for physical therapy, and (3) when physical therapy is applied efficiently on the basis of a definite prescription and is continued no longer than it is really indicated. On the basis of these principles, cooperation with insurance carriers may be established and opportunities for good work by qualified and ethical physicians developed.

Well informed members of the medical profession have come to realize that physical therapy measures belong to the therapeutic armamentarium of the educated physician, that their efficiency when applied in suitable cases with the proper technic has been definitely established. It behooves leaders of medicine in states and counties to safeguard the interests of public health and of the medical profession by encouraging or actively promoting educational work which will lead to a more widespread and more rational use of physical therapy by the medical profession in general.

Council on Pharmacy and Chemistry

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association held its annual meeting at the headquarters building, 535 North Dearborn Street, Chicago, Friday and Saturday, March 2 and 3, 1934. Those present were Dr. Stanhope Bayne-Jones, Dr. E. M. Bailey, Dr. H. N. Cole, Dr. Eugene F. Du Bois, Dr. C. W. Edmunds, Dr. Morris Fishbein, Dr. Reid Hunt, Dr. Ernest C. Irons, Dr. Paul Nicholas Leech, Dr. Lafayette B. Mendel, Dr. G. W. McCoy and Dr. W. W. Palmer.

Dr. Reid Hunt was reelected chairman of the Council and Dr. Torald Sollmann was reelected vice chairman.

Among the many items discussed during the meeting, the following may be of interest to both physicians and manufacturers.

Mutual Problems of the Council on Pharmacy and Chemistry and the Committee on Foods.—The Council discussed the matter of permissible claims for the various vitamins both as foods and as drugs. It was brought out that the Committee on Foods in its meeting had agreed not to permit, either on labels or in advertising, any claims for vitamin E, the so-called antisterility vitamin. The Council instructed the chairman to appoint a committee to study and report on the prophylactic and curative claims that can be recognized for each of the vitamins, particularly for vitamins B and C.

The Council discussed the question of a vitamin product the manufacturer of which wishes to include the word "certified" in the name. It was suggested that the word "assayed" might be permissible, but the referee for vitamin products pointed out that all accepted products are assayed. It was the consensus that the use of the word "certified" in the name of such a product is misleading and cannot be permitted.

Lay Advertising of Iodine Preparations for Goiter Prophylaxis.—A number of years ago the Council voted that lay advertising of iodine preparations for prophylaxis against goiter be permitted. During the past year the question was again raised in connection with the reconsideration of two accepted preparations, Iodostarine-Roché and Iodo-Casem (Sharp & Dohme), both of which have dosage forms of chocolate coated tablets containing 0.01 Gm. of iodine.

The possibility of self medication with such preparations was discussed. In discussion of the possibility of activation from the use of iodine preparations it was pointed out that this usually occurs in cases of nodular goiter in persons over 35 years of age who have been taking doses as large as 10 grains (0.65 Gm.) of potassium iodide daily for some period. It was the general opinion that any danger from the lay advertising of such prophylactic preparations as those under discussion might be avoided by adequate caution as to dosage and, further, that the matter of instructing the public in proper goiter prophylaxis is of high importance. The Council decided to reaffirm its previous action in permitting the lay advertising of iodine prophylactics against goiter, the advertising propaganda to be subject to approval by the Council's Committee on Therapeutics.

Radio Advertising of Accepted Products.—It was brought out that the Council's office has received a complaint concerning statements made in radio broadcasts advertising an accepted preparation. The manufacturer was asked to inform the Council what statements had been authorized. In reply, the firm sent a list of statements concerned directly with the Council acceptance of the product, but not the entire text of the advertising broadcast. Members of the Council found some of the statements objectionable in that they implied Council "approval," whereas according to the Council's rules acceptance does not mean recommendation of a product. Another objection was concerned with the firm's statement that the product was accepted by the A. M. A., whereas it is only the Council that does the accepting. In the discussion it was brought out that for effective control it is necessary that the complete text of radio broadcasts be considered. It was pointed out that the question of radio

broadcasts concerning Council-accepted products must necessarily be an increasing one, and means for adequate control were discussed.

It was decided that all firms doing radio advertising of Council-accepted products be informed that the Council feels obliged to pass on the complete text of all radio broadcasts before they are released to the public over the air, and that adequate arrangements will be made for prompt action on such advertising copy.

The Use of Therapeutically Suggestive Terms on Labels.—The Council does not permit the use of disease names on labels or in circulars for accepted products that lend themselves to self medication. Last year the Council voted that the terms "sedative" and "hypnotic" on labels for barbituric preparations be not permitted and that the same shall apply to folders accompanying trade packages but not to advertising literature to be sent to physicians. The question has arisen whether or not terms similar in therapeutic implication to "sedative" and "hypnotic" should have similar consideration for instance, "sedative and soporific," "cardiac stimulant," "diuretic," "anodyne," "antiseptic," "emollient."

In the discussion it was questioned whether or not entire prohibition of such terms would be the proper action, and the consensus was that such drastic action is not required. It was voted that the Council allow such designations in general but prohibit them where they appear to be distinctly harmful or tend to drug habituation by suggesting self medication.

Bismuth Preparations for the Treatment of Syphilis.—The Council's referee for bismuth preparations reported that manufacturers are submitting advertisements advocating the use of their preparations in the treatment of every form of syphilis, alone or in combination with arsphenamines. The referee favored recommendation for the use of these in any stage of syphilis but only in conjunction with arsphenamines and/or mercury preparations.

New and Nonofficial Remedies states that, although a few syphilologists are treating syphilis with bismuth compounds alone, sufficient evidence has not yet been produced to indicate that the use of bismuth preparations alone is efficacious. In order that there may be a clear understanding and particularly to aid in passing on future advertisements, the referee asked for general discussion of this matter.

After due consideration it was voted to put on record the decision that the Council is at present opposed to the use of bismuth compounds alone in the treatment of syphilis.

The referee further stated that there are several manufacturers who advance the claim that their respective compounds are absorbed in toto without change in the local tissues and that proof has not been furnished for this claim. It was felt that firms making this claim should be required to furnish evidence that any bismuth salt used therapeutically is absorbed unchanged—that so far such proof has been lacking. It was the consensus that this was a matter of demonstrable proof and that, until satisfactory evidence has been presented, no claim of absorption in unchanged form be allowed. The referee felt that any bismuth preparation is helpful in neurosyphilis but stated that he did not know whether this necessarily means that the bismuth is present in appreciable amounts in the spinal fluid and in the tissues. Although no specific action was taken on this point it was the general opinion that until more definite evidence is available the Council should disallow all claims of particular penetration into the central nervous system of bismuth compounds.

Lay Advertising of Halibut Liver Oil with Viosterol.—In the case of viosterol in oil 250 D, the Council has held that the preparation was so potent in vitamin D activity that it should be used only with the advice and under the guidance of a physician. Therefore, advertisements of viosterol in oil 250 D to the public have not been permitted.

The secretary reported that the advertising department of THE JOURNAL had recently inquired whether or not halibut liver oil (plain) or halibut liver oil with viosterol 250 D could be advertised in *Hygeia*. It was pointed out that halibut liver oil with viosterol 250 D is just as potent antirachitically as viosterol in oil 250 D, it was further pointed out that the plain halibut liver oil has an excess potency of vitamin A over cod

liver oil comparable to the excess potency in vitamin D of viosterol in oil 250 D over plain cod liver oil. The Council's referee for vitamin products expressed the opinion that the high vitamin A potency of halibut liver oil makes this product as ineligible for lay advertising as does the high vitamin D potency of viosterol in oil 250 D. The advertising department was informed that neither plain halibut liver oil nor halibut liver oil with viosterol 250 D could be advertised to the public without recommendation by the Council. As a result of the discussion, it was voted to continue the Council's rule that products as potent in vitamin activity as 250 D be not permitted to be advertised to the public at the present time.

Revision of New and Nonofficial Remedies Articles on Preparations Containing Vitamins A and/or D—The Council discussed the action to be taken in view of the forthcoming promulgation of the unitages, standards, and so on, for vitamins A and D adopted as an interim revision by the Pharmacopoeial Revision Committee. After considerable explanatory comment, the Council's referee offered the following tentative revision for the article "Cod Liver Oil and Cod Liver Oil Preparations" (N N R 1933, p 270, 1934, p 275, beginning with line 12 of the first paragraph)

The Pharmacopoeia (U S P \ Revised 1934), besides giving tests for the purity of cod liver oil also gives methods for the assay of its content of vitamin A and vitamin D; furthermore it provides that the vitamin A potency and vitamin D potency of cod liver oil when designated shall be expressed in United States Pharmacopoeia units per gram of oil and may be referred to as U S P units per gram of oil. It is also stipulated that

One United States Pharmacopoeia unit of vitamin A is equal in growth promoting and antixerophthalmic activities for the rat to one international unit of vitamin A as defined and adopted by the Conference of Vitamin Standards of the Permanent Commission on Biological Standardization of the League of Nations in June of 1931. One United States Pharmacopoeia unit of vitamin D is equal in antirachitic potency for the rat to one international unit of vitamin D as defined and adopted by the Conference of Vitamin Standards of the Permanent Commission on Biological Standardization of the League of Nations in June of 1931.

For purposes of information it may be stated that the new U S P unit of vitamin A is equivalent to 0.714 unit U S P \ (1925) the new U S P unit of vitamin D is equivalent to 3.26 A D M A units, or 0.370 so-called Steenbock units.

The Pharmacopoeia (U S P \ Revised 1934) now specifies that cod liver oil must contain in each gram at least 600 U S P units of vitamin A and at least 85 U S P units of vitamin D. Cod liver oil may be flavored by the addition of not more than 1 per cent of any one or any mixture of flavoring substances recognized in this pharmacopoeia.

Evidence has accumulated to show that it is feasible to market cod liver oil having a vitamin A potency much higher than the lower limit of the pharmacopoeial product. Accordingly all brands in New and Nonofficial Remedies are required to have a vitamin potency of at least 850 vitamin A units per gram and at least 85 vitamin D units per gram when tested by the U S P \ (Revised 1934) method.

It has been shown that an effective concentrate of cod liver oil can be made and marketed. To be acceptable for inclusion in New and Nonofficial Remedies such a concentrate should have a vitamin A potency of at least 14,000 U S P \ (Revised 1934) units per gram or 1,160 U S P \ (Revised 1934) units per tablet or other dosage unit and a vitamin D potency of at least 1,400 U S P \ (Revised 1934) units per gram or 110 U S P \ (Revised 1934) units per tablet or other dosage unit.

The Council requires that the vitamin A and vitamin D potency of accepted brands of cod liver oil and cod liver oil concentrates be declared in U S P \ (Revised 1934) units on the label of such products. Statements of the potency of tablet preparations of cod liver oil concentrate made on a per tablet basis and also on a per gram of tablet basis should appear in the firm's presentation and in New and Nonofficial Remedies. On the labels however a declaration of vitamin potency per tablet is sufficient.

The average daily dose of U S P \ (Revised 1934) cod liver oil recommended by the U S P Vitamin Advisory Board is as follows:

Average Daily Dose	
Infants	12 cc (3 fluidrachms)
Adults	24 cc (6 fluidrachms)

The consensus of the replies to a questionnaire on the subject indicates that the figures given represent the prophylactic and curative dose when the new U S P cod liver oil is used.

The referee then recommended that the following sentence be deleted from the article "Viosterol" (N N R 1933 p 427, first paragraph, N N R 1934, p 433 first paragraph)

The Council has also adopted the qualifying phrases 250 D 10 D etc to designate the vitamin D potency of the various preparations as multiples of the vitamin D potency of a cod liver oil of definite potency as determined by the rat assay method.

In explanation of this recommendation the referee pointed out that the designation "D," for example "10 D" no longer seems appropriate. The designation of the strength of viosterol should

either be given in terms of U S P X (Revised, 1934), units of vitamin D, or the equivalent of such figures as "10 D" should be added to the earlier designation, for example, "250 D" equals 9,000 U S P X (Revised, 1934) or "10 D" equals 360 U S P X (Revised, 1934) units.

After discussion of the referee's recommendations, the Council voted that this revision be published in the midsummer supplement to N N R, furthermore, that these standards be taken as standards not only for cod liver oil but for all preparations sold primarily for their content of vitamins A and D. Finally, the suggestion was made that the manufacturers who cooperate with the Council be informed of the action so that they may provide suitably for making changes in their advertising and promotional material just as soon as the Pharmacopoeia officially adopts these standards.

Glandular Therapy—It was reported that there is still a demand for the Council's book *Glandular Therapy*, which was first published in 1925 and revised in 1927. The book is now out of date. It was decided that a new edition should be published, and the chairman appointed a committee of three to draw up a list of individuals who might be asked to prepare such articles as may be needed in this field, to be published in THE JOURNAL, under the auspices of the Council, and then issued in book form. The editor of THE JOURNAL declared his willingness to cooperate in this project.

Protein Therapy—The secretary reported that the Council office is in receipt of increasing numbers of inquiries concerning nonspecific protein therapy. The subject is changing, because more recently the proteins used are being chemically treated by use of formaldehyde, nitrous oxide, and so on, rather than heat treated. The suggestion was made that it might be timely for a series of articles to be published under the auspices of the Council, dealing with nonspecific protein therapy. The suggestion met with approval and it was the general consensus that it is not necessary to have a series of articles, but one extended article dealing with protein therapy.

Bacillus Acidophilus Therapy—The Council's referee reported the progress of an investigation, sponsored by the Council, to determine the bacterial qualities of *Bacillus acidophilus* products. He hoped in the near future to report on the Council accepted *B. acidophilus* preparations in the light of this investigation.

Transfer of Radium and Radium Preparations to Purview of the Council on Physical Therapy—The secretary reported the request of the Council on Physical Therapy that the consideration of radium products be transferred to that body. The matter was discussed at length and it was agreed that such transfer is desirable. The Council voted that the consideration of radium compounds, applications and other devices be transferred from the purview of the Council on Pharmacy and Chemistry to that of the Council on Physical Therapy on Sept 1, 1934, and that should the internal use of radium be recognized at some future time, such preparations be considered under the purview of the Council on Pharmacy and Chemistry or the joint purview of the two councils.

Toxicity of Cinchophen and Related Compounds—From time to time the Council has pointed out the dangers inherent in the use of cinchophen and related drugs on account of their toxicity. At this time the question was raised as to whether in the interest of the public and the medical profession the Council should withdraw its recognition of the drug. It was pointed out that the greatest danger to the public arises from the use of cinchophen when masked or undeclared in proprietary mixtures such as the Council does not recognize. A member warned against a possible conclusion that neocinchophen is essentially safer than cinchophen pointing out that there is no available evidence to that effect. It was the general opinion that physicians should be educated to the use of this dangerous drug, as in the case of other dangerous drugs that if the Council were to withdraw recognition of all drugs which cause accidents, there would be little left for inclusion in a book such as New and Nonofficial Remedies. The Council voted to retain cinchophen in New and Nonofficial Remedies unless and until more definite reasons for its omission are available.

Reports of the Committees—Among the more noteworthy reports were those of the Committee on Nomenclature and the Committee on Rules and Procedure. The chairman of the

Committee on Nomenclature emphasized the fact that the matter of permission to use proprietary names and the use of numbers and letters for names are frequent and troublesome problems that come before the Council. He felt that the only manner in which such policies can be enforced at all is to enforce them literally and rigorously.

The chairman of the Committee on Rules and Procedure reported difficulty in interpreting the recently revised rule providing that the Council would not consider articles when they were "not found in the open market." He questioned whether the interpretation should be restricted to exclude wholesale packages on shipments. The Council voted that the present rule be reaffirmed with the understanding that the term "open market" contemplates both the wholesale and retail dispensing of drugs.

This committee report also reviewed the application of the Council's rule 11, which reads:

The Council will not accept or retain if already accepted the articles of a firm if in the opinion of the Council the policies of such firm are clearly detrimental to the welfare of the public and to medicine.

The Council continued the current discussion of the application of this rule to three firms. In the case of two of those the decision to apply the rule was reaffirmed. In the case of the third firm, it was decided to make further inquiry to determine whether the firm might be agreeable to withdrawing non-acceptable products from the market.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

RAYMOND HERTWIG Secretary

IRON CLAIMS FOR FOODS

Foods vary considerably in iron content, only a portion of which may be readily utilized. The value of a food for meeting nutritional needs for iron depends (1) on its iron content, (2) on the availability of the iron and (3) probably on the presence of sufficient traces of copper in the diet to insure an efficient utilization of the iron. The ability of the growing body to get iron depends on the nutritive value of the diet in other respects besides iron. A well constructed diversified diet adequate in all other respects is likely to be ample in iron and copper for normal adults. Rapidly growing children need relatively more iron than adults, and their diets should always contain some foods rich in this element.

To warrant an iron claim, a food in an amount that most adults would consume easily in a single day should furnish a substantial proportion of the daily iron requirement (approximately 15 mg. Fe). Any food that would result in an intake of less than 3 mg. of iron (as Fe) per day does not warrant special recognition in advertising.

Iron claims should be restricted to simple statements of the value of the product in comparison with common foods for contributing iron for dietary needs. They should not involve statements of any order pertaining to blood building, because of their therapeutic significance or implications.

BLOOD BUILDING CLAIMS IN ADVERTISING

Iron is an important element in blood formation, since it is a chemical component of hemoglobin, the coloring substance of red blood corpuscles. Other substances taking part in hemoglobin generation are pigment-complexes, parent substances of the hemoglobin molecule, and copper in minute traces. It is important to point out that iron, copper and the pigment-complexes are concerned only with hemoglobin formation. They in no way contribute to the many other constituents of the blood some of which are in solution as other mineral salts, proteins, amino acids and dextrose, and some in suspension as white blood corpuscles, platelets and the stroma of red blood corpuscles. Even the red blood cell stroma is only indirectly affected by iron and copper. In secondary or nutritional anemia the red

corpuscles decrease because they have no pigment to carry. Their number will increase, however, with an increase of hemoglobin, provided there is no impairment of the cell forming mechanism. It is thus evident that the food supply of iron and copper affects only the hemoglobin content of blood.

The whole process of blood regeneration is complex, involving many factors that may be affected by pathologic or disease conditions as well as by adequacy or inadequacy of the diet in iron. Anemia is a condition in which the blood is deficient in hemoglobin. It may be due to an inadequate diet, but pathologic conditions are frequently involved. Anemia and blood regeneration are not appropriate subjects for advertising addressed to the public. Blood building claims, therefore, should be excluded from food advertising.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

VETA-RONI

Manufacturer—Prince Macaroni Mfg. Company, Boston.

Description—Macaroni prepared from durum wheat semolina, soya bean flour, yeast and salt.

Manufacture—Durum wheat semolina, soya bean flour, yeast and salt with sufficient water are thoroughly mixed in a dough mixer, kneaded in a kneading machine and forced through dies to produce the desired forms (sea shells and spaghetti), which are dried and automatically packed in glassine bags.

Analysis (submitted by manufacturer) —	per cent

BEECH-NUT STRAINED APRICOTS

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved apricots (dried without use of sulphur dioxide) retaining in high degree the natural mineral values but little of the vitamin C content of apricots.

Manufacture—California apricots, dried without the use of sulphur dioxide, are washed, soaked for two to three hours and cooked in glass-lined kettles in vacuum for about thirty minutes. The subsequent sieving and processing are the same as for Beech-Nut Strained Carrots (THE JOURNAL, Nov. 11, 1933, p. 1562).

CURTISS EASY ACES CANDY

Manufacturer—Curtiss Candy Company, Chicago

Description—Chocolate coated candy The coating contains sucrose, chocolate and cacao butter The inside contains sucrose, corn syrup, hydrogenated coconut fat, egg albumin, cocoa, salt, gelatin, and flavor (vanillin, tonka beans and coumarin)

Manufacture—The corn syrup and sucrose are melted and mixed with gelatin, albumin and water All ingredients in formula proportions are whipped in a beating machine to a maximum volume The mass is spread on steel plates, chilled and cut into pieces, which are chocolate coated, cooled to harden and wrapped

(1) M S C BRAND FANCY GOLDEN
TABLE SYRUP

(2) M S C BRAND CRYSTAL WHITE
TABLE SYRUP

Distributor—Merchants Service Corporation, San Francisco California, Chicago and New York

Packer—D B Scully Syrup Company, Chicago

Description—(1) This syrup is the same as the accepted Banner Blue Corn Syrup with Cane Flavor (THE JOURNAL March 5, 1932, p 817), table syrup, corn syrup base (85 per cent) with refiners' syrup (15 per cent)

(2) This syrup is the same as the accepted D B Scully White Crystal Syrup (THE JOURNAL, April 15, 1933 p 1174) table syrup, corn syrup base (85 per cent) with rock candy syrup (15 per cent), flavored with vanillin and coumarin

HAWAIIAN FINEST QUALITY PINEAPPLE
JUICE (UNSWEETENED)

- (1) GOOD MORNING
- (2) LUCKY BOY BRAND
- (3) RIVAL
- (4) SNOWBALL BRAND
- (5) SUNBEAM
- (6) UNITED BRAND
- (7) WHITE VILLA

Distributors—(1) Good Morning Co Operators, Terre Haute Ind (2) Embassy Grocery Corporation New York (3) Rival Foods, Inc., Cambridge, Mass (4) G E Howard & Company, Newburgh, N Y (5) Austin Nichols & Company Inc New York (6) United Grocers Company Brooklyn (7) White Villa Grocers, Inc., Cincinnati and Dayton Ohio

Packer—Hawaiian Pineapple Company Ltd San Francisco

Description—Canned Hawaiian pineapple juice retaining in high degree the natural vitamin content, the same as the accepted Dole Hawaiian Finest Quality Pineapple Juice (Unsweetered) (THE JOURNAL June 3 1933, p 1769)

McCORMICK'S BEF BRAND PURF FOOD COLOR
A SOLUTION ALCOHOL 10%

- (a) BLUE, (b) BROWN, (c) GREEN (d) PEACH (e) PINK
(f) RED (g) VIOLET (h) YELLOW

Manufacturer—McCormick & Company Inc Baltimore

Description—Aniline colors in 10 per cent alcohol solution respectively (a) brilliant blue F C F (b) Tartrazine 640 80 Ponceau 3R, Fast Green F C F (c) Tartrazine 640 and Fast Green F C F (d) Orange I 150 and Tartrazine 640 (e) Erythrosine 773 and Amaranth 184 (f) 80 Ponceau 3R (g) Amaranth 184 and Fast Green F C F (h) Tartrazine

640 and Orange I 150, certified by the United States Department of Agriculture for use in foods

Manufacture—Aniline colors, certified by the United States Department of Agriculture for use in foods, are dissolved in distilled water, alcohol is added, and the solution filtered and bottled

<i>Analysis</i> (submitted by manufacturer) —	per cent
Moisture and alcohol	97.7
Total solids	2.3

SATURDAY, APRIL 21, 1934

DEATHS OF PHYSICIANS PUBLISHED IN 1933

During 1933 the total number of obituaries published in THE JOURNAL was 3,354, which includes 145 Canadians. The deaths of 3,209 physicians of the United States were recorded, as compared with 3,142 in 1932 and 2,952 in 1931. The list includes 3 who died in the Philippines, 3 in China and 1 each in Hawaii, Puerto Rico, Central America, South America, Mexico, France, the Netherlands, Japan, Persia and Africa. The obituaries of 83 women physicians were published, as compared with 87 in 1932. The graduates of medical schools in the United States for the fiscal year ended June 30, 1933, numbered 4,895. Deducting the number of physicians whose obituaries were published, there was a net addition to the ranks of the profession for the year of 1,686, which, figured thus, is a decrease of 108 from 1932.

Ages—The average age at death of those classified as of the United States was 64.4, as compared with 64.1 for 1932. Two physicians lived to be 100 years old and 46 others lived to be 90 or more. Thirty-one physicians died between the ages of 25 and 29, 38 between 30 and 34, 68 between 35 and 39, 96 between 40 and 44, 179 between 45 and 49, 271 between 50 and 54, 379 between 55 and 59, 510 between 60 and 64, 445 between 65 and 69, 446 between 70 and 74, 345 between 75 and 79, 229 between 80 and 84, and 122 between 85 and 89. The month with most deaths was January, with 301.

Causes—Heart disease was again the leading cause of death, with 1,131 fatalities as compared with 1,101 for 1932. Some contributory causes are included in the tabulation, as they have been in former years. A report that the cause of death was "chronic nephritis and heart disease," for example, is so published in THE JOURNAL and is recorded on the statistical charts under both diseases. Of the deaths from heart disease, endocarditis or myocarditis was specified in 292, angina pectoris in 107 and pericarditis in 1. Cerebral hemorrhage was the second most frequent cause

reported, with 360 deaths, 18 additional deaths were reported as due to paralysis. Pneumonia was the third most frequent cause, lobar pneumonia was reported in 236 cases and bronchopneumonia in 77. Fourth on the list was cancer. Of 286 deaths caused by cancer, the stomach and liver were affected in 66 cases, the prostate gland in 32, the intestine in 27, the buccal cavity in 2, the female genital organs in 1 and the skin in 1, in 157 the part affected was not specified. Arteriosclerosis caused 248 deaths, and other diseases of the arteries 7, embolism and thrombosis caused 204, nephritis 194, of which 18 cases were specified as acute nephritis, uremia 79, diabetes 69, influenza 62, tuberculosis 56, and other diseases of the respiratory system 5, diseases of the prostate 43, and other diseases of the genito-urinary system 24, hypertension 41, appendicitis and senility 40 each, peritonitis and cirrhosis of the liver 33 each, septicemia 27, intestinal obstruction 23, and other diseases of the digestive system 28, ulcer of the stomach 21, hemorrhage 19, pernicious anemia and brain tumor 15 each, leukemia 14, gangrene and biliary calculi 13 each, asthma 12, granulocytopenia, cholecystitis and paralysis agitans 11 each, meningitis 10, chronic bronchitis 9, diseases of the liver 9, erysipelas 8, arthritis, encephalitis and hernia 7 each, pleurisy, goiter and Hodgkin's disease 6 each, cellulitis 5, benign tumors, aneurysm, diseases of the veins, softening of the brain, dementia paralytica and toxemia 4 each, undulant fever 3, Ludwig's angina, empyema, myasthenia, pellagra, epilepsy, sinusitis, otitis media, malaria, tabes dorsalis, drug addiction and mental diseases 2 each. Among other unusual causes of death given for 1 case each were typhoid, typhus, Addison's disease, actinomycosis, myelitis, paratyphoid, bronchopulmonary moniliasis, chronic muscular atrophy, acute dysentery, pancreatitis, linitis plastica, coccidioid granuloma, amebiasis, Raynaud's disease, ileus, multiple neuritis, exposure, Banti's disease, atrophic biliary cirrhosis, esophageal varices, pulmonary infarct, heat prostration, diphtheria, chronic poliomyelitis, food poisoning, lymphoblastoma, hypothyroidism, fracture, shock, tumor of the spinal cord, ruptured gallbladder and ruptured esophagus.

Accidental Deaths—One hundred and forty-eight physicians died as the result of accidents in 1933, compared with 158 in the previous year. Automobile accidents accounted for 75 deaths, 2 less than in 1932. In 1933, deaths from falls numbered 32, the second largest number due to accidental causes. Seven deaths were caused by drowning, 5 by burns, 4 by airplane accidents and 3 each from train accidents, overdoses of medicine, shooting and illuminating gas and skull fracture, and 1 each by injury to the hip, x-ray burns, electrocution, carbon monoxide poisoning and explosion. One physician met death by being kicked by a horse, and 1 by being gored by a bull. One was killed when he fell down an elevator shaft, 1 died as the result of hemorrhage due to strain sustained while

cranking a car, and 1 of laceration of his throat by a foreign body. In one case the nature of the accident was not specified.

Suicides and Homicides—Suicide was the cause of 70 deaths in 1933, 17 less than in 1932. Shooting accounted for 35 of these deaths, poison for 15, hanging and drugs 4, incised wounds and gas poisoning 3 each, jumping and chloroform 1 each, and in the remaining cases the method was not reported. There were 10 homicides by shooting, 2 by stabbing, 1 by poisoning and 1 victim was beaten.

Positions—Among the decedents were 157 who were or had been teachers in medical schools, 291 who served in the World War, 45 veterans of the Civil War, and 47 veterans of the Spanish-American War. Ninety-one had been health officers, 86 members of boards of education and 63 members of boards of health. There were 49 coroners, 44 mayors of municipalities, 21 members of state legislatures, 22 members of state boards of medical examiners, 17 members of the U. S. Army Medical Corps and 6 of the U. S. Navy Medical Corps. Twenty-nine bank presidents, 18 druggists, 17 authors, 14 missionaries, 12 members of city councils, 9 editors, 6 postmasters, 5 clergymen, 5 dentists, 2 lawyers, 1 congressman, 1 U. S. Senator, and 1 justice of the peace were included.

Association Officers—The obituaries published in 1933 of physicians who were or had been officers of the American Medical Association included 2 vice presidents, 3 trustees, 8 section officers and 4 members of councils. Twenty-one members or former members of the House of Delegates died during the year. Thirty-five presidents or former presidents of state societies and 5 state secretaries were included among the officials.

ABSORPTION AND EXCRETION OF SILICA

Although dust per se was early mentioned as a cause of pulmonary disease, and despite the fact that there has long been a tradition of hazard in the quarrying and cutting of granite and other silicious stone, according to McNally¹ it was not until 1860 that a demonstration was made of silica in lung tissue. An occupational disease of wide distribution, silicosis presents a unique problem in industrial hygiene. In spite of the numerous alleged causes of the disease, the primary factor in its etiology is still considered to be the inhalation of silica dust.² Not only is it extremely difficult to prevent or control the development of silicosis, but the details of the administration of modern industrial compensation constantly raise questions of cause of death and of culpability in proved cases.³ In bringing to bear

modern methods of research on the solution of this pressing problem in public health, it is obvious from long experience that recourse to experimental studies on lower animals is a most promising if not the only direction in which progress can be made. Of particular interest in this regard, therefore, are the recent investigations carried out by King, Stantial and Dolan⁴ in the Banting Institute at the University of Toronto.

After a quantitative method for the estimation of small amounts of silica had been devised, the concentration of this substance in body fluids and tissues was studied. The amount of silica in human urine and in the urine of cats and dogs was much less than that in herbivorous urine. That this situation is in large part referable to the intake of silica in the food was demonstrated by feeding rabbits on oats, carrots and wheat straw in one case and on white bread and tomato in the other. The urine contained from 12 to 27 mg. of silica per hundred cubic centimeters on the first ration and only from 0.7 to 4 mg. when the more refined food was consumed. The ubiquitous distribution of this substance is emphasized by its occurrence in the eggs of birds and in mammalian fetal tissues. It appears therefore, that soluble compounds of silicon are a more or less normal constituent of body fluids. Adult tissues as might be expected, vary considerably in their silica content; normal spleen contains about 15 mg. per hundred grams of dry tissue and normal lung about 140 mg. McNally states that a lung containing more than 200 mg. of silicon dioxide per hundred grams of dried tissue can be classed as silicotic.

The mechanism also of the excretion of silica was examined by the Toronto investigators. Suspensions of fine quartz dust were given by stomach tube; there was a prompt increase in the level of silica in the urine and this lasted for more than six hours. Essentially the same response was elicited when silicic acid was administered orally. It is striking that, despite the evidence of transport from the gastro-intestinal tract to the kidney, the amount of silica in the blood was changed little if any from the low normal concentration. In another experiment, silicic acid was given intravenously over a period of six hours. The urinary silica increased and there was an appreciable rise in the concentration of silica in the blood, but though the level of excretion in the urine was augmented for forty hours after the injection stopped, only about half of the silica given was accounted for.

In order to simulate the usual mode of entrance into the body, silicic acid was inspired by the experimental animal; in every case there was observed a moderately increased output of silica through the kidney. These studies have a bearing on a biochemical phenomenon long recognized but never entirely adequately explained, namely the solution and metabolism in the body of chemical compounds, like silica, which in the laboratory

are noted for their resistance to chemical treatment. The foregoing studies indicate that silicon is absorbed and is promptly excreted from the body through the kidneys, i. e., the renal threshold for this element or its compounds is low.

THE LONGEVITY OF THE ERYTHROCYTE

"Without doubt, the red corpuscles have, like all other parts of the organism, a tolerably definite term of existence, and in a like manner die and waste away when the portion of work allotted to them has been performed."¹ This is a characteristic textbook statement that recognizes a "birth and decay" of the erythrocytes without formulating the details, which would be extremely interesting. How long do the colored corpuscles survive before they disintegrate? Unfortunately, one cannot earmark an erythrocyte and follow its fate in the circulation or in some secluded organ. Several indirect methods of estimating the longevity of the red cells have been applied experimentally. One of these has been to note the output of a bile pigment, bilirubin, a derivative of hemoglobin, as an index of erythrocyte destruction. The inadequacy of this plan has been discussed by several competent observers. Various factors are known to affect independently the amount of bilirubin secreted. Another procedure has been measurement of the time requisite for replacement regeneration after removal of a known fractional part of the hemoglobin or of the corpuscular volume.

From hemoglobin regeneration rates, Whipple and Robbins² have estimated that 115 Gm. of hemoglobin constitutes the portion destroyed each week as normal functional "wear and tear" (maintenance factor) in dogs having a blood volume of approximately 550 cc. They indicate that the blood overturn requires about five weeks. This approach to a solution of the problem has been criticized because studies on erythrocyte regeneration show that the hemorrhage preceding regeneration constitutes a supernormal stimulus to the erythrogenic marrow, so that fractional parts of the blood after hemorrhage are undoubtedly replaced more rapidly than equivalent parts under normal "wear and tear." Escobar and Baldwin³ of the University of Southern California, having recorded their objection to all of the preceding plans, suggest that the longevity of the erythrocyte in mammals may be determined by increasing the erythrocyte volume in the circulation by means of short exposure periods to low pressures of oxygen. The number of days elapsing from the end of the exposure period to the attainment of the normal red cell volume (or count) indicates approximately the duration of life of the erythroplastid in the circulation. The experiments on man were carried out after a sojourn for several days at altitudes

of from 9,000 to 10,500 feet. The longevity of the erythrocytes was thus found to be between eighteen and thirty days.

If this is even an approximation to the truth, it is evident that the hematopoietic apparatus must be kept rather busy during the three-score years and ten allotted to man.

Current Comment

REGISTRATION OF COLLEGES UNDER HARRISON NARCOTIC ACT

Medical colleges use opium and coca leaves and their derivatives and compounds primarily to familiarize students with the properties of such drugs, a use approximating that to which they are put by practitioners of medicine. They may use them, however, to a certain extent, for research and experimental purposes. Colleges other than medical colleges use them solely for such purposes, which approximate, according to a recent ruling of the acting commissioner of internal revenue,¹ the use of such drugs by compounders of them more closely than their use by practitioners. Medical colleges, therefore, may ordinarily be registered under the Harrison Narcotic Act as "practitioners," on payment of the annual tax for that class of registrants, \$1. When colleges, whether medical colleges or not, use such drugs for analytic and experimental work, they must be registered as "compounders" and pay the annual tax for that class, \$24 a year. Collectors of internal revenue have been instructed to ascertain, in the registration of educational institutions, the purpose for which narcotic drugs are to be used, in order to insure proper registration and tax payments.

LOSS OF HEAT FROM EXTREMITIES

The arms and legs of man are customarily thought of primarily in connection with their functions of prehension and locomotion. However, the characteristic shape of these appendages and the fact that they extend out into the surrounding atmosphere render them of particular importance in connection with those physiologic activities related to skin surface. It has been calculated that approximately two thirds of the entire surface of the body is accounted for by the area of the arms, hands, legs and feet. As about 75 per cent of the heat loss from the body takes place through conduction, radiation and convection from the skin surface, it might reasonably be expected that the extremities would assume an important role in both the conservation and the loss of heat. A recent study by Maddock and Coller¹ has yielded quantitative data bearing on this point. The movement of blood toward or away from the body surface in various localities was measured in human subjects by determining the skin temperature. Heat is produced by metabolic chemical reactions in the body and brought to the surface by the blood, where it is dissipated. It was observed that an

increase in the surrounding temperature was accompanied by an augmented skin temperature, the extent of the change was least on the skin of the forehead and trunk and greatest in the extremities. The dissipation of heat was more marked in the legs than in the arms and increased distally. The influence of the basal metabolic rate on heat loss was similarly examined in both normal and abnormal individuals. Here again an increased heat production was accompanied by a higher level of heat loss and the topographic distribution again emphasized the significance of the extremities in this respect. The toes seem especially responsive to the necessity of the body to lose heat, there was demonstrated a linear relationship between the basal metabolic rate and the dissipation of heat from the skin of the great toe. It appears that the exigencies of temperature control require movements of blood of considerable magnitude to and from the periphery. This circumstance accounts, in part, for the changes in volume of the extremities—the swelling in summer and the shrinkage in winter. As body heat must be conserved in winter and heat is lost with particular readiness from the arms and legs, one may well view with some apprehension the current habits of dress which encourage the omission of stockings from the costume, especially among little children, whose temperature equilibrium is none too secure at best.

A CONSULTATION SERVICE FOR PATIENTS OF MODERATE MEANS

(Report of the First Two Years)

GEORGE BAHR, M.D.
NEW YORK

Because of the growing complexity of modern medicine, the general practitioner frequently requires additional diagnostic facilities to supplement his own resources, as well as the advice and guidance of more experienced internists and specialists. Persons of very limited means, who constitute the great majority of private patients can usually afford the additional services of a single specialist or a roentgen or other laboratory examination, if the family physician can be sure which one will solve the diagnostic or therapeutic problem. But the cost is often prohibitive for this class of patients if the condition requiring investigation is clinically obscure and requires multiple consultations and laboratory examinations in order to establish a diagnosis. The patient is then apt to gravitate from his private physician to the public wards of a hospital both for diagnosis and for therapy.

In order to keep this class of patients out of the wards and in the hands of their family physicians the medical staff of the Mount Sinai Hospital in cooperation with the trustees of the hospital, inaugurated an experiment about two years ago the details of which have been published¹ in *THE JOURNAL*. A consultation service was established for patients of moderate means differing in the following respects from other diagnostic clinics

1 It was organized by the medical staff as an independent detached unit of the hospital—not as part of a dispensary.

2 No patients are accepted unless referred by their physicians.
3 The economic level of eligibility is limited by a maximum income of \$2,400 a year for unmarried individuals and \$4,000 a year for total family income.

4 The work is limited exclusively to diagnosis.

5 No therapy is practiced, on completion of the clinical investigation the patient is returned to the referring physician with as complete a diagnostic opinion as possible, together with detailed advice concerning appropriate therapy.

6 The internists, surgeons and specialists are the members of the visiting staff of the hospital proper.

7 A minimum of 50 per cent of the gross income is available to remunerate the medical staff.

8 A flat fee of \$35 is charged for all patients regardless of the nature of their illness or the number of consultations or laboratory examinations required.

9 To avoid interference with the practice of individual consultants, the fee is set at about double the average amount charged patients of this class by a specialist for an individual consultation or major laboratory examination.

10 The hospital derives no profit, directly or indirectly, from the operation of the consultation service.

The project was designed as an experiment in placing the professional and physical facilities of a large, well equipped general hospital at the disposal of the practicing physicians of the community for the benefit of their patients of moderate means. At the time of inauguration of the consultation service it was decided that the experiment would be tried for a period of two years. Its continuation thereafter was to depend on whether its need had been established by the volume of work and the number of physicians in the community who had utilized its facilities during this period, and whether its successful operation had been carried on without evidence of conflict or criticism from the physicians of the community or the members of the medical staff of the hospital.

The present report is now made at the termination of the preliminary trial period of two years. The verdict of the medical staff of the hospital is indicated by the fact that most of them have referred patients and have voluntarily participated in the work of the consultation service, including heads of the clinical departments whenever the nature of the diagnostic problems warranted their services.

The place which the Consultation Service of the Mount Sinai Hospital has achieved in the community is indicated by the

number of physicians who have referred patients to it. During the two years of its operation more than 1,000 physicians referred almost 2,000 patients for investigation.

Because of the cosmopolitan character of the city and its large transient population a similar tabulation of patients would show a much wider distribution. It would not give as accurate an idea of the source of work as the tabulation of the geographic distribution of the physicians from whom the patients were received.

As shown in table 1 457 of the 1,090 physicians who referred patients to the consultation service practice in Manhattan

	1932	1933
Gross Income	\$30,192.40	\$33,215.00
Donations	50.00	
	\$30,242.50	\$33,215.00
Fees to clinicians	\$15,236.25	\$16,700.77
Salaries to employees	6,221.53	6,021.68
Operating costs*	14,023.06	16,625.71
Net operating loss	5,142.63	5,517.87
Loss per patient	6.94	6.86

* Operating costs include an equitable part of the cost of services shared with other departments (laboratories, maintenance, telephone, bookkeeping, laundry, insurance) but no capital or interest charges.

As is indicated in table 2 two thirds of the patients (1,335) were received from 473 physicians, the number referred by each of these men varying from two to fifty-six. This group may therefore be regarded as the regular clientele. The physicians who referred the largest numbers practice as a rule among the poor, but some of the best patrons of the service were medical consultants and specialists. They referred patients of limited means whom they had seen in consultation with family physicians and on whom they had been unable to make a diagnosis. They would otherwise have been obliged to send these patients into the public wards of a hospital for study.

In spite of the financial depression and the amount of unemployment among this class of the population, the number of patients investigated during 1933 was slightly more than in the previous twelve months (seventy-three). Furthermore, no steps were taken during the year to remind physicians of the existence of the service. As a matter of fact, considerably more patients were referred by their physicians in 1933 than in 1932, but at least 25 per cent were obliged to cancel their appointments because they were unable to pay the fee of \$35. As the operating deficit was \$5,517.87, or about \$5.86 per patient, and the diagnostic service is therefore rendered at less than cost, the fee seems to be fair.

Although the consultation service was operated at a loss of \$5.86 per patient, the cost is small if compared with the value of the services rendered to the patients and to the community. To the physicians who referred patients, the consultation service functioned as more than a mere guide to an understanding of the medical problems and the treatment of the individual cases. To many it has served as a form of postgraduate education, keeping them abreast of the modern methods of diagnosis and therapy.

The consultation service may be regarded as a contribution to the study of the widely discussed problem of 'the costs of medical care,' concerning which there has been much talk and but little experiment. Many of the patients would previously

have found their way into the wards of the hospitals. The cost of the diagnostic investigation both to the patients and to the hospital would have been much larger. None of the physicians who participated in the clinical studies would have been compensated for their services and the family physicians would have risked the permanent loss of their patients. The patients, if employed, would have been prevented from earning their living during the period of hospitalization which, one can assume, would have averaged at least ten days. At the ward rate of \$3 a day, the diagnostic investigation would have cost them at least \$30. At the same time the cost of this patient to the hospital would have been about \$3 more a day than the maximum ward rate or a total of not less than \$30 per patient compared with a net cost of \$5.86 per patient in the consultation service.

The service has been protected as far as possible from abuse by the fact that patients are accepted if referred by physicians who have been acquainted with the economic limitations of eligibility, and the patients are interrogated before admission. To our knowledge the service has rarely been abused. This is indicated by the fact that only one patient in about 2,000 subsequently entered the private pavilion of the hospital for a short period, although a great many who were found to require hospitalization for operation or special forms of therapy were referred by their physicians to the semiprivate and public wards.

By furnishing a diagnostic service of unlimited thoroughness at low cost to persons of limited means, the institution has given these patients a type of complete service which they could not otherwise have secured or it has enabled them to conserve their slender resources for the subsequent treatment of their disease. In this manner it has undoubtedly enabled a large number of physicians to retain private patients whom they might have lost to the public wards and clinics.

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Thirtieth Annual Meeting held in Chicago Feb. 17 and 18, 1934
(Continued from page 1234)

DR. G. M. WILLIAMSON, Grand Forks, N. D., in the Chair

THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

Traffic in Narcotics by Licensed Physicians

MR. H. J. ANSLINGER, Washington, D. C. One of my duties as Commissioner of Narcotics is to determine, with the advice of the United States Public Health Service, the quantities of crude opium and coca leaves that shall be imported into the United States under the Narcotic Drugs Import and Export Act. No supply of these drugs is permitted to be imported for other than medical and scientific needs, and no morphine, codeine or cocaine or any other opium or coca leaf derivative may be imported under any circumstances.

The average normal medical need of the United States, in the absence of epidemic conditions, is represented by 120,000 pounds of crude opium and approximately 225,000 pounds of coca leaves. The average total sales of morphine and codeine, the more important opium derivatives, are about 100,000 ounces of the former and about 140,000 ounces of the latter per annum. Almost the entire quantity of these drugs is dispensed or prescribed by the medical profession, although an appreciable quantity is manufactured into the so-called exempt preparations which may be sold directly to the consumer for medical purposes by the retail druggist.

Restriction of the manufacture, sale and use of narcotics to medical needs is not only an independent national policy, as

outlined in the provisions of the federal narcotic laws but also a definite international obligation under the Hague Opium Convention of 1912 and the more recent Manufacturing Limitation Convention of 1931.

Under the Harrison law there are about 150,000 registrants in the practitioner class, which includes physicians, dentists, veterinary surgeons and hospitals. It gives me pleasure to report that, with respect to the great majority of these, little, if any, difficulty is had in the matter of due observance of the federal narcotic laws. Some practitioners, however, step over the borderline of ethics and sell or dispense narcotics without reference to bona fide professional practice. About three years ago I caused to be made an informal survey of persons registered as practitioners or druggists, concerning whom there were reasonable grounds for believing that drug addiction existed. The names of about 1,700 such registrants were furnished, most of them being in the practitioner class. The survey made in this country checks with a recent survey made in Germany, which reported to the League of Nations in April 1932 that the prevalence of addiction in the medical profession reached one in every 100. In the general population of the United States the Public Health Service has estimated that there is about one addict in every 1,000. In the general population in Germany there is an addict in every 10,000, according to their German survey. The bureau seeks the assistance of the state boards in eliminating these sources of diversion of narcotic drugs by revocation of licenses to practice theretofore issued to the offending physicians. Some of your boards have no power to revoke licenses for narcotic violations. We did report to the state licensing boards over the period from Oct 1, 1930, to Dec 31, 1932, the names and the facts in the cases against 360 physicians who had been convicted of violating the federal narcotic law, and of 302 other physicians who were found to be narcotic drug addicts according to our investigations. Twelve additional physicians were also reported who had not been convicted but against whom there was evidence of gross narcotic irregularities. We have only reported the flagrant cases, and we have tried to be fair. Of those 705 cases reported, there were revoked, 39 suspended 5, placed on probation, 24, admonitions, 20, dismissed no action taken 66, not licensed, 42. I want to make special mention of the effective action taken in cases involving narcotic irregularities by California and Oregon and, particularly at this time to express our appreciation for the intense cooperation of Dr Pinkham. We have received a fair degree of cooperation from Colorado, Illinois and Kansas, but, generally, the results have been discouraging and I wish to solicit your valuable cooperation to the end that prompt action may be taken in all cases to eliminate the unfit members of the profession when the facts justify the procedure.

DISCUSSION

DR WALTER L. TREADWAY, Washington, D. C. More satisfactory results in the professional use of habit-forming narcotic drugs might be obtained through the medium of instruction to professional students and to practitioners, and through the medium of an authoritative memorandum for guidance in this problem. It is probable that a great deal may be accomplished in this field through a concerted educational program within the profession. Such an educational program bears upon the subject of preventing further addiction. The desirability of a concerted educational program becomes more apparent when it is realized that the abusive use of habit-forming narcotic drugs is widespread throughout the United States. Drug addiction constitutes a medicosocial problem of importance. Although federal agencies are charged in law with certain functions respecting this medicosocial problem it is nevertheless of sufficient importance to enlist the support of local and state governments, of local state and national associations and particularly of those agencies concerned with licensing and regulating the practice of medicine. Experiences have indicated that ambulatory treatment of drug addiction is unsound and impracticable of application. The experiences of clinics established in New York and other places throughout the country for the purpose of furnishing addicts with drugs in nondiminishing doses proved impracticable and undesirable.

The migration of addicts to the areas served by these clinics an increased traffic in drugs occasioned by the policy, and the abuses and conniving of officers, addicts and others made it necessary for the federal government eventually to condemn the practice. Sometimes well meaning but misguided physicians have, through sympathy, furnished addicts with drugs to satisfy addiction and subsequently found themselves overwhelmed with individuals demanding drugs. As a result, the physician accidentally finds himself in the position of a trafficker in these substances. An educational program may prevent these accidents. The Federation of State Medical Boards can be of great assistance in these matters.

DR H. M. PLATTER, Columbus, Ohio. I should like to ask Mr. Anslinger whether, in case a physician has been convicted of a violation of the narcotic law, federal officers have the right to withhold from him his narcotic permit, or is it necessary for state boards to suspend or revoke it in order to protect him?

MR. ANSLINGER. We have not the power to withhold registration of any doctor who wants to register, after conviction, or carry on and order narcotics after conviction. We have no power to stop him. He may go down to the Collector of Internal Revenue and get his tax stamp. Sometimes the court orders the man not to register for a certain period.

DR PLATTER. Suppose we cite a man before a state hearing for revocation or suspension of his license and he agrees with us not to reapply for a permit except with our endorsement. Could that be done?

MR. ANSLINGER. He could register nevertheless.

DR T. J. CROWE, Dallas, Texas. I want to compliment Mr. Anslinger for the work he has done for the medical profession. Last November we had before the Texas board forty men who were addicts. Commissioner Anslinger had his force in our meeting to present the evidence on these men, as a result of which we revoked the licenses of seven and have thirty on probation. Commissioner Anslinger and his department refuse to give a narcotic permit to any practitioner of Texas who is not registered in the state board, which is a wonderful help.

DR E. J. ENGBERG, St. Paul. I hope that the department will in the future furnish us as promptly as possible the names of all whose licenses are revoked in any of the states for drug addiction or violation of the narcotic law. If we get that information quickly we are justified in acting, but if it comes six years after conviction it is not proper that we should take any more action than to get in contact with that man and let him know that he is under supervision.

MR. ANSLINGER. We are going to prepare a list of the physicians whose licenses have been revoked in the several states and send them out to the state medical boards.

DR WALTER L. BIERRING, Des Moines, Iowa. May I ask to what extent narcotic permits are issued to osteopathic physicians?

MR. ANSLINGER. It depends on the law of the particular state. For instance, if under the state law the osteopath is permitted to handle narcotic drugs and he is licensed by the state board he can be registered under the Harrison act, but that is something which must be corrected in the state laws. We have no power to deny registration to osteopaths when the state law permits it.

DR BIERRING. In Iowa they are operating under a previous ruling of the attorney general permitting osteopaths to prescribe morphine.

MR. ANSLINGER. That holds true in other states.

DR G. M. WILLIAMSON, Grand Forks, N. D. In North Dakota the attorney general of the state ruled that an osteopath could not prescribe drugs or use narcotics so all the narcotic licenses or permits that had been issued to osteopaths in North Dakota were recalled. Osteopaths cannot get a permit in North Dakota.

DR W. C. WOODWARD, Chicago. The rule is that if a person is authorized by state law to prescribe narcotic drugs the Bureau of Narcotics and the Commissioner of Internal Revenue of the United States have no authority but must register him. If the courts of the state have interpreted the

state law, then the interpretation of the courts is binding. However, if the attorney general, in the absence of a court decision, has interpreted the state law, I believe you will find that the opinion of the attorney general will be binding until some one raises the issue in the courts of the state.

DR J W BOWERS, Fort Wayne Ind. In Indiana we rely on court findings because they appeal their case, and it is always reversed, or invariably so. We cannot suspend but must revoke, and we can always make it stick under those circumstances.

MR ANSLINGER. A compromise is always an admission that one can go through with the prosecution. Cases are compromised for a number of reasons. Sometimes witnesses are in another jurisdiction or have died or have left the service. We never compromise a case unless the United States attorney definitely makes a statement that he does not believe the case should be prosecuted.

DR IRVIN D METZGER, Pittsburgh. In Pennsylvania our chairman of the bureau reported to us some time ago that there are seventy-five doctors of the state on this list of suspected addicts. We have established this regulation in our hospitals, so far as interns are concerned, that no dose of narcotics shall be repeated excepting after the patient has been seen by a physician in a hospital, an intern probably, and the chief shall check up when he returns the following day, to see whether or not he approves that prescription. In other words, that is not permitted to be determined by the nurses. Let us get these young fellows started right and we shall have relatively little trouble with them later. We have had to revoke a number of licenses, in all cases we have had the heartiest cooperation by the federal department. The worst cases are the traffickers, fellows that simply have no conscience in the matter and who have no sense of responsibility, and, believe me, that is the last type of person that should practice medicine of any kind.

MR ANSLINGER. Outside of Pennsylvania, California is the only state where there is a central state agency to which the federal government can go and put its problem on the table. In the other states there isn't any central body to which we can go. In some states the state board of health is supposed to administer the law, but we don't have any particular individuals like the man in charge of your bureau and like the man in charge of the bureau in California where we have almost weekly correspondence about certain cases.

The Use of the Injunction Procedure in Enforcing Medical Practice Acts

F MANLEY BRIST, LL B, St Paul. A writ of injunction for the purpose of this discussion, may be defined as an order of court forbidding the defendant to engage in the practice of medicine unless he is lawfully licensed so to do. The writ forbids the practicing and makes the defendant liable to punishment for contempt of court if he thereafter engages in the practice, contrary to the order of the court. Several states are using this method of regulating the practice of medicine so far as nonlicensed individuals are concerned, the outstanding example perhaps being the state of Iowa.

Every one engaged in the enforcement of laws pertaining to the practice of medicine without a license is familiar with the difficulties encountered, some of which are: 1 Lack of cooperation on the part of local authorities. 2 Misguided confidence reposed in quacks by persons in the local community. 3 Delay in bringing the defendant to trial with the result that invariably he continues to practice in the meanwhile. 4 Difficulty encountered in convincing some juries beyond a reasonable doubt that the law has been violated and that the defendant is guilty. 5 Disadvantage of the state not having the right to appeal in the event of an adverse decision.

The most frequent objection offered by the defendants to the use of the injunction is that it deprives them of a trial by a jury. The use of the writ of injunction involves the obtaining of sufficient evidence on the part of the state to make out a prima facie case that the defendant is engaged in the unlawful practice of medicine. The facts are usually presented to the court in the form of a petition or bill in equity praying that a writ of injunction issue against the defendant. The writ is

served on the defendant and requires him to appear in court at a specified time. The matter is then heard on the merits by the court without a jury.

The use of the injunction to control the unlawful practice of medicine has demonstrated in several states that it has many advantages, some of which are that it (1) affords a speedy remedy in a civil proceeding before the court without a jury, (2) gives the state the right of appeal in the event of an adverse decision in the lower court, (3) produces greater cooperation between state and local enforcement agencies, (4) still leaves available criminal prosecution if necessary or desirable, (5) minimizes the likelihood of "local influence" and (6) is less expensive to the state by eliminating jury costs.

DISCUSSION

DR CHARLES E HUNISTON, Chicago. In Illinois the quo warranto proceeding has been run through to a very logical end and the records are available to any state board that would like them. The whole thing is in a form that is ready to be served up in any court. The practice of medicine by a corporation is illegal in every state because a corporation cannot qualify. What are we going to do in the case of corporations? Quo warranto is effective if it is followed up. The injunction might be part of the follow up, and the injunction is effective. One way or another, warfare on the medical underworld should be more active. I do not share all of this peaceful attitude of letting criminals have their way.

DR W C WOODWARD, Chicago. Lest the representatives of our boards of examiners go home with too great expectations of what they may accomplish by the use of injunction proceedings, I call attention to the fact that where injunction proceedings have been successful, with a single exception so far as I know, they have been based on statutes. If you are going to be successful in your proceedings under the laws relating to injunctions, the first thing that is requisite is to go to your legislatures and procure adequate statutes for that purpose. The law does not prohibit the practice of the healing arts but the most that it can do is to regulate it. So the law says only that a person who desires to practice medicine may do so, but he must do so under these conditions and in the following manner, and that is as far as the state is able to go. The very basis of the injunction proceeding is to proceed against a person for something he has not done, in other words, it is to prevent him from doing something that will work an injury that cannot be satisfied by prosecution criminally or cannot be satisfied by damages in civil prosecution. Under those conditions the law says that the court may enjoin this person from working this injury. Obviously, if there is anything that cannot be satisfied by payment in damages, it is the loss of life or the loss of health. It is worth while for you to go home and examine your medical practice acts and your statutes relating to the issue of injunctions to see whether it may not be expedient to ask for legislation that will enable you to proceed along that line.

GEORGIA

Hospital News—A medicolegal unit will be added to the laboratories of clinical pathology in the department of pathology at Grady Hospital, Atlanta under the direction of Dr Jack C Norris, associate professor of pathology and public health Emory University School of Medicine The chemical function of poisons will be studied in the new unit

Society News—Dr Montague L Boyd presented a paper before the Fulton County Medical Society, April 5 on "Anatomy of Prostatic Hypertrophy and Resection of the Prostate Through the Urethra" Dr John Funke gave a clinical talk on 'The Increased Metabolic Rate Due to the Effect of Intestinal Intoxication on the Thyroid Gland'—The Clarke County Medical Society was addressed in Athens February 2, by Drs William H Cabanis and Henry W Birdsong, Athens on 'Inflammatory Conditions of the Eye and Reduction of Difficult Fractures' respectively—At a recent meeting of the Macon Medical Society Dr Roy R Kracke, Emory University spoke on 'Agranulopemic State'—Dr George S Murray Columbus addressed the Randolph County Medical Society in Cuthbert March 1 on 'Treatment of Chronic Arthritis'

ILLINOIS

Society News—A symposium on acute intestinal obstruction constituted the meeting of the Adams County Medical Society in Quincy, April 9, with Drs James F Merritt, Frank Cohen, Ralph McReynolds and Earl L Cuddick as speakers

Chicago

University News—Chumcev D Lenke, Ph D, professor of pharmacology, University of California Medical School, San Francisco, gave the first annual Phi Beta Pi lecture under the auspices of the University of Chicago Medical Schools and Delta Chapter of Phi Beta Pi, April 12, at Billings Hospital, on "The Relations of Medicine and Fine Art"

Memorial for Dr Williamson—Funds are being solicited to establish a memorial in honor of the late Dr Charles Spencer Williamson, professor of medicine at the University of Illinois College of Medicine. It is hoped to accumulate a fund of \$500 for a suitable portrait of Dr Williamson, to be hung in the library of the university, and a sum between \$5,000 and \$10,000 to establish a lectureship in internal medicine. The dean of the medical school has approved the plan and the committee, composed of Drs Carroll C L Birch, Ernest S Moore and Adolph Hartung, chairman, urges former patients, students and colleagues of Dr Williamson to contribute. Dr Williamson who was associated with the medical school for thirty one years, died Feb 15, 1933

Society News—Drs Harry L Parker, Rochester, Minn., and Arno B Luckhardt, among others, addressed the Chicago Neurological Society April 19 on "Traumatic Encephalopathy in Professional Pugilists" and "Physiology and Pathological Physiology of the Pituitary Gland and Adjacent Structures," respectively—Drs Julius H Hess and Otto Saphir, among others, addressed the Chicago Pediatric Society, April 17 on "Celac Disease—A Series of Pathologic Studies"—Carl R Moore, Ph D, and Dr William Harcourt Browne addressed the Chicago Gynecological Society, April 20, on "Hormones in Relation to Reproduction" and "Use of Follutem in Dysmenorrhea," respectively—Speakers before the Chicago Society of Internal Medicine, April 23, will be Drs Robert W Keeton, on "Effects of Diets Low in Calories Containing Varying Amounts of Protein on the Weight Loss and Metabolic Rate of Obese Patients", William F Petersen, "Clinical Significance of Pressor Episodes", and Alexander J Nedzel, "Experimental Production of Vegetative and Ulcerative Endocarditis"

INDIANA

Society News—A symposium on medical legislation will be presented before the Indianapolis Medical Society, April 24, by Drs William N Wishard Sr, Frank W Cregor, Indianapolis, and William R Davidson, Evansville—Dr William E Lower, Cleveland, spoke before the Tiptecanoe County Medical Society in Lafayette, April 12, on "Endocrine Factors in Prostatic Function"

Annual Graduate Meeting—The third annual graduate educational meeting of the Indiana State Medical Association will be a joint session with the First District Medical Society at the Elks Home, Evansville, April 26. The following physicians, among others, will participate in the program

Willis D Gatch Indianapolis Value of Postgraduate Study
Harry P Ross, Richmond Obstetrical Mortality in General Practice
Carl E Badgley Ann Arbor Mich Orthopedics for the General Practitioner
Albert F Clements Evansville Ear Pain and Its Causes
Burton D Myers Bloomington The Anatomy of the Endocrines
Roscoe L Sensesich South Bend Interrelationship of the Endocrine Glands
Earl A Menninger Topeka Kan Psychoanalysis and Neuropsychiatry
Leon G Zerfas Indianapolis New Developments in Diagnosis of Blood Disturbances
Ralph L Lochry Indianapolis Value of X Rays to the General Practitioner
Cleon A Nafe Indianapolis Methods of Diagnosing and Handling Acute Surgical Problems

Dr Roy Wesley Scott, Cleveland will be the dinner speaker on "Some Observations on Heart Disease"

IOWA

Personal—Dr Charles W Sanders, Northwood, completed fifty years in the practice of medicine, March 7—Dr Jacob Breid physician and superintendent of the Sac and Fox Tuberculosis Sanatorium, Toledo, since Jan 1, 1920 retired from active service April 1, having reached the age limit of 65 years. Dr Ira D Nelson, formerly superintendent of the Indian Hospital at Claremore, Okla succeeded Dr Breid

MAINE

Typhoid at Augusta—Newspapers reported, April 2, that forty cases of typhoid with three deaths had occurred in Augusta after a milkman's son contracted the disease by drinking water from the Kennebec River. Seven members of the milkman's family took the disease and all cases in families served by this dealer were traced to milk distributed by him. More than 4,000 persons in the city and its environs were inoculated. A special isolation ward was established at the Augusta General Hospital

MARYLAND

Full Time County Health Service—With the appointment of Dr Louis S Welty as health officer of Caroline County, all the counties in the state are now on a full time health basis. There are twenty-three counties in Maryland.

Society News—Dr Leonid Andreyev, who has been conducting research work at McGill University, Montreal for two years, addressed a meeting at the Phipps Clinic, Baltimore, March 7, on conditional reflexes—A symposium on the autonomic system was presented before the Baltimore City Medical Society, February 2, by Drs Bertram M Bernheim, Raymond A Taylor, Thomas P Sprunt and Philip Bard, Ph D—Dr Richard P Strong, Boston, delivered the guest lecture in medicine at the meeting of the Johns Hopkins Medical Association in Baltimore, February 23, on "Clinical and Public Health Aspects of American Onchocerciasis"

Mental Hygiene Clinics—The first of a series of mental hygiene clinics, planned by a group of Maryland psychiatrists as a special project, was held in Salisbury, March 2. The state has been divided into districts, with three or more counties in a district. Principal efforts will be directed toward children. Physicians are working as a volunteer group and are not connected with any state activity in this project. Some physicians, particularly heads of institutions, are expected to delegate much of the actual work to their staffs. Those in charge of the clinics are

Dr J H Mason Knox Jr, chief bureau of child hygiene state department of health
Dr Ralph C P Truitt director Maryland Mental Hygiene Clinic and executive secretary Mental Hygiene Society of Maryland
Dr Esther L Richards, associate professor of psychiatry Johns Hopkins University School of Medicine Baltimore
Dr Ross McC Chapman professor of psychiatry, University of Maryland Medical School Baltimore
Dr Robert E Garrett superintendent Spring Grove State Hospital
Dr Hosea W McAdoo superintendent Springfield State Hospital
Dr Manfred S Guttmacher, chief medical officer Supreme Bench of Baltimore
Dr George H Preston, commissioner of mental hygiene of Maryland

MICHIGAN

Graduate Courses—April 15 marked the opening of a series of graduate courses sponsored by the department of postgraduate medicine of the University of Michigan Medical School and the Michigan State Medical Society. The initial course is a medicomilitary refresher course and will extend to April 28. Others in the series are

Ophthalmology and Otolaryngology University Hospital Ann Arbor April 23-28
Diseases of Metabolism University Hospital Ann Arbor May 21-26
Clinic on Speech Defects Northern Michigan Children's Clinic Marquette April 26
Proctology Receiving Hospital Detroit May 28
Obstetrics Gynecology and Gynecological Pathology Receiving Hospital Detroit June 4-9
Practitioners' Course Receiving Hospital Detroit June 18-23
Surgical Diagnosis Receiving Hospital Detroit June 25-30

Society News—Dr Norman F Miller, Ann Arbor, addressed the Kalamazoo Academy of Medicine, March 20, on "Complications of Parturition"—A symposium on the disturbances of menstruation was presented before the Wayne County Medical Society, April 16, by Drs Lewis E Daniels, Harold Henderson and Milton A Darling. Dr Malcolm T MacEachern, Chicago, will address the surgical section of the society, April 23, on "Individual Responsibility of the Physician to Organized Medicine and Advancement in His Scientific Knowledge"—Speakers before the Tuscola County Medical Society, March 8, in Caro were Drs Edward Dowdle and W P Woodworth, Detroit, on "Acute Abdominal Conditions" and "Common Problems of Ophthalmology"—Dr Clyde K Hasley, Detroit, spoke before the Livingston County Medical Society, March 2, on skin diseases and their treatment—At a meeting of the Calhoun County Medical Society, March 6, Dr Joseph Brennemann, Chicago, discussed treatment of emphysema in children

District Conferences—The Michigan State Medical Society and the department of graduate medicine of the University of Michigan Medical School, Ann Arbor, sponsored

a graduate conference in the eleventh district at Muskegon, March 21, with the following program

- Dr. Dewey R. Heeders, Grand Rapids: Acute Infections of Throat and Neck
- Dr. Charles I. Brown, Ann Arbor: Recent Factors in Treatment of Cardiac Lesions
- Dr. Eugene B. Potter, Ann Arbor: Acute Lesions of the Abdomen
- Dr. Thomas D. Gordon, Grand Rapids: Recent Measures in Prevention and Treatment of Acute Infectious Diseases
- Dr. William J. Butler, Grand Rapids: Acute Infections of the Urinary Tract

At a similar conference in the thirteenth district in Petoskey, March 8, Dr. Albert C. Furstenberg, Ann Arbor, discussed "Acute Suppurations of the Mouth, Pharynx and Cervical Region" and "Tumors and Cysts of the Head and Neck." Dr. Raphael Isacacs, Ann Arbor, "Diagnosis Symptoms and Treatment of Anemia," and Dr. Norman F. Miller, Ann Arbor, "Obstetrical Emergencies" and "Postnatal Care." A public meeting in the evening was given over to discussion of "Preventive Measures for Community Health." The names of the speakers were not available.

MISSISSIPPI

Society News—A recent meeting of the Central Medical Society was addressed by Drs. James B. Anderson, Yazoo City, on "Diagnosis and Treatment of Sacro-Iliac Arthritis," James T. Rainer, Yazoo City, "Treatment of Intracranial Hemorrhage," and Gilruth Darrington, Yazoo City, "Gonorrhea in the Male."—Speakers before the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg, March 13, included Drs. Thomas E. Wilson Jr., Jackson, on "Blood Supply of the Heart," Doctor A. Pettit, Vicksburg, "Pyelitis," and Preston S. Herring, "The Handling of a Normal Obstetric Case."—A symposium on cancer constituted the meeting of the Northeast Mississippi Thirteen Counties Medical Society in Pontotoc, March 20, with Drs. Giles S. Bryan, Amory, and Shields Abernathy, Memphis, Tenn., as the speakers.—Speakers before the Tri-County Medical Society (Copiah, Lincoln and Walthall) included Drs. Edwin E. Benoit, Natchez, on diseases of the gallbladder, and Richard S. Savage, Brookhaven, significance of laboratory interpretation. The next meeting will be held in Tylertown in June.

MISSOURI

State Medical Meeting at St. Joseph, May 7-11—The seventy-seventh annual meeting of the Missouri State Medical Association will be held at St. Joseph, May 7-11, under the presidency of Dr. Warren L. Allee, Eldon. Lecture sessions will be at the Robidoux Hotel and clinical sessions at the Missouri Methodist Hospital. Guest speakers include Drs. Walter L. Biering, Des Moines, President-Elect, American Medical Association, on "Coronary Artery Disease," George H. Ewell, Madison, Wis., "Carcinoma of the Prostate," Dean M. Lierle, Iowa City, title to be announced, John H. Musser, New Orleans, "Treatment of Diseases of the Blood," and Charles M. Swab, Omaha, "Ocular Complications of Gonorrhea." Missouri physicians who will participate in the program include the following:

- Arthur Glenn Davis, Senath: Tertian Malaria with Unusual Type of Skin Manifestations
- Rutherford B. H. Gradwohl, St. Louis: The Blood Platelet Count and Postoperative Venous Thrombosis
- Jonas Curtis Lyter, St. Louis: A Working Basis for the Therapeutics of Angina Pectoris
- Wilson A. Myers, Kansas City: Diaphragmatic Hernia with Special Reference to Esophageal Hiatus Hernia
- George Wise Robinson Jr., Kansas City: The Neurotic—A Challenge
- William J. Stewart Jr., Columbia: Abduction Traction Treatment of Congenital Dislocated Hips

Rev. Alphonse M. Schwitalla, Ph.D., dean, St. Louis University School of Medicine, St. Louis, will address a public meeting. Table demonstrations will be an innovation in the program this year and will be conducted by Drs. Frederick B. Campbell, Charles C. Dennis, Edward H. Skinner and Delon A. Williams, all of Kansas City. The Buchanan County Medical Society will entertain the association Wednesday evening and other entertainment planned will include a golf tournament and a trap shoot.

NEW JERSEY

Bills Passed—The following bills have passed both the assembly and the senate: S. 94, proposing to amend the law providing liens in certain cases for hospitals by raising to 50 cents the fee required to be paid on filing a claim of lien; and A. 245, to amend the dental practice act by proposing among other things, to add to the grounds on which a license to practice dentistry may be revoked, a violation of any of the

rules or regulations which the state board of registration and examination in dentistry may hereafter adopt with respect to the practice of dentistry.

NEW MEXICO

Personal—Dr. George H. Buer, Mountain Air, was appointed health officer of Torrance County, February 21, to succeed Dr. James H. Wiggins, Estancia.

NEW YORK

Bill Introduced—A resolution, introduced in the senate by Mr. Esquirol on April 9, and referred to the committee on finance, proposes to create a joint legislative committee to study the laws of New York, of the United States and of foreign countries relative to narcotic drugs and to recommend to the legislature such revision, if any, of the laws of New York as may be necessary.

Bills Passed—The following bills have passed the assembly and the senate: A. 417, to amend the pharmacy practice act by proposing (1) that a drug shall be deemed to be misbranded within the meaning of the act if the package fails to bear a statement of the percentage contained therein by quantity of barbituric acid and (2) that the act shall not apply to the manufacture and sale of proprietary medicines except those containing poisons deleterious and/or habit-forming drugs and chemicals, A. 1377, proposing to prohibit a corporation from using the word "doctor" or "Dr." as a part of its corporate name.

Personal—Dr. William S. Hartigan has been appointed police and fire surgeon of Rochester, succeeding Dr. John A. Stapleton, who retired after thirty-four years in the position.—Dr. Henry W. Tobias, recently clinical director of the veterans' facility at Newington, Conn., has been made chief medical officer of the new facility at Batavia.—Dr. James E. Perkins, for several years epidemiologist on the staff of the Minnesota Department of Health, has been provisionally appointed to a similar position with the New York State Department of Health.—Dr. Edwin A. Simonds, Carthage, completed fifty years in the practice of medicine, March 1.

Society News—Drs. Robert L. Dickinson and Eric M. Matsner, New York, addressed the Medical Society of the County of Nassau, Mineola, February 27, on "The Doctor as Marriage Counselor" and "Certain Aspects of Maternal Welfare," respectively.—Dr. Russell L. Cecil, New York, addressed the Medical Society of the County of Westchester at Valhalla, February 20, on "Serum Treatment of Pneumonia."—Dr. James A. Cahill, Jr., Washington, D. C., addressed the Chemung County Medical Society, Elmira, February 8, on "Acute Diseases of the Abdomen."—At the meeting of the Medical Society of the County of Albany, February 28, Dr. Rudolph Ruedemann, Jr., spoke on "Diagnosis and Treatment of Early Syphilis," and Drs. Victor C. Jacobson and Arthur W. Wright reviewed recent advances in laboratory sciences.—Dr. Edward C. Reifstein, Syracuse, addressed the Jefferson County Medical Society, Watertown, March 8, on treatment of anemias.—The New York State Association of Public Health Laboratories will hold its eighteenth annual meeting at the University of Rochester School of Medicine and Dentistry, May 7.

New York City

Bronx County Lectures—To take the place of its scientific meetings which have been temporarily discontinued, the Bronx County Medical Society has inaugurated a program of afternoon lectures at various hospitals. The first series, dealing with obstetrics, is as follows:

- March 22: Dr. Maurice O. Magid: Prenatal Care
- March 29: Dr. Irving Smiley: Management of Normal Labor
- April 5: Dr. Harry Aranow: Toxemia of Pregnancy
- April 12: Dr. Samuel S. Rosenfeld: Hemorrhage During Pregnancy
- April 19: Dr. Murray L. Brandt: Prevention and Treatment of Sepsis
- April 26: Dr. Milton J. Goodfriend: Indications and Use of Forceps

Dr. Anna Williams Retired—Dr. Anna W. Williams, assistant director of laboratories in the New York City Department of Health since 1905, was retired March 23, having passed the age limit for city employees. She will continue her research in the laboratories on a pension. Dr. Williams was graduated from the Women's Medical College of the New York Infirmary for Women and Children in 1891 and for several years practiced in New York, spending some time also in graduate study in Europe. In 1895 she became bacteriologist in the health department and in 1905 was appointed assistant to Dr. William H. Park. She is the author of "Pathogenic Microorganisms," collaborated with Dr. Park as author of "Who's Who Among the Microbes" and has contributed many articles to scientific periodicals.

Committee on Chronic Illness—Creation of a committee of medical authorities and social workers to plan and put in action a program for better care of the chronically ill in New York has been announced by the Welfare Council. This action is the result of a survey made recently in which it was shown that there are at any time 70,000 persons in the city incapacitated by chronic illness. Provision for care of this large section of the population was found to be inadequate. The committee wishes to create new attitudes in the public, develop better facilities for care and more adequate coordination of services for prevention and cure of chronic illness. Medical members of the committee are Drs. Ernst P. Bois, George Baehr, Margaret S. W. Barnard, Mark L. Fleming, John E. Jennings, William Ropes May, Herbert B. Wilcox and I. Ogden Woodruff.

Society News—Dr. Hugh Cabot, Rochester, Minn., addressed the New York Society of the American Urological Association, April 4, on "Effect of Drainage by Nephrostomy upon Kidney Function."—A symposium on transplantation of tissue was presented before the American Society of Plastic Surgeons at a meeting at the New York Academy of Medicine, April 3, by Drs. Fred H. Albee, Karl Winfield Ney, Walter A. Coakley and Maxwell Maltz.—Drs. Elliott C. Cutler, Boston, and Nathaniel P. Rathbun addressed the Medical Society of the County of Kings, March 20, on "Experiences with Total Thyroidectomy for Heart Disease" and "Present Status of Operative Procedures for Obstructive Lesions of the Neck."—Dr. Isador W. Kahn addressed the Society of Medical Jurisprudence, February 13, on "Medicolegal Aspects of Criminal Abortion in New York City."—Dr. Oswald S. Lowsley addressed the International Association of Industrial Surgeons, March 1, on "Low Back Pain as Related to Urologic Pathology."—A symposium on recent progress in leukemia research was presented at a meeting of the New York Pathological Society, April 5, at which speakers were Drs. Richard H. Jaffe, Chicago, Lloyd F. Craver, Maurice N. Richter and Jacob Furth.—A symposium on methods of treatment available to the general practitioner in the field of otolaryngology was presented at a meeting of the Medical Society of the County of New York, March 26, by Drs. Samuel J. Kopetzky, Marvin F. Jones and Charles J. Imperatori.

OKLAHOMA

Personal—Dr. Charles E. White, Muskogee, has been appointed health commissioner of Muskogee County to succeed Dr. Edwin H. Coachman, resigned.—Dr. Charles M. Pearce, McAlester, has resigned as health commissioner of Pittsburg County to engage in private practice.

Academy of Medicine Organized—The Muskogee Academy of Medicine was organized at a meeting, February 9, for the promotion of scientific medicine in the territory of Muskogee. The first scientific program was held April 5, with the following guest speakers: Drs. Willis C. Campbell, Memphis, Tenn., on fractures of the femur and orthopedic principles, Arthur B. Chase, Oklahoma City, heart disease, and John Zahorsky, St. Louis, pediatrics.

Society News—Dr. Leroy Long, Oklahoma City, addressed the Craig County Medical Society, February 6, on "The Bile Tract Area."—Dr. E. Albert Aisenstadt, Picher, discussed management and treatment of burns before the Okfuskee-Okmulgee County Medical Society, Henryetta, in February.—Dr. Richard B. Ford, Holdenville, addressed the Hughes County Medical Society, Calvin, February 9, on diseases of the gallbladder.—At a meeting of the Carter County Medical Society in Ardmore, March 5, speakers were Drs. Leonard S. Willour, McAlester, on benefits of organized medicine, Arthur W. White, Oklahoma City, peptic ulcer and Leroy Long, Oklahoma City, toxic goiter.

PENNSYLVANIA

Society News—The Medical Society of Cumberland County met, March 13, at the Army Field Service School, Carlisle, at the invitation of the commandant, Gen. Matthew A. Delaney. Dr. Henry P. Carter, Dr. Morrison C. Staver and Lieut. Paul E. Zuver spoke on medicomilitary subjects.—Dr. Francis C. Grant, Philadelphia, addressed the Northumberland County Medical Society, March 7, on "Treatment of Cranial Trauma."—Dr. Burton T. Simpson, Buffalo, addressed the Berks County Medical Society, Reading, February 13, on "Responsibility of the Medical Man in the Control of Cancer."—The Montour County Medical Society met at the Danville State Hospital, March 16, with Drs. Henry F. Hunt, Sydney J. Hawley and Robert R. Hays as speakers on blood dyscrasias.—Dr. deWayne G. Richey, among others, addressed

the Pittsburgh Academy of Medicine, March 13, on "Pneumococcus Pseudomembranous Pharyngitis."—Dr. Howard L. Stitt, Cincinnati, addressed the Erie County Medical Society, Erie, March 6, on bronchiectasis.—Dr. Elliott B. Edie, Uniontown, read a paper on "Spontaneous Hyperinsulinism" before the Fayette County Medical Society, Uniontown, March 1.—Dr. Henry M. Ray presented a paper before the Pittsburgh Urological Society, March 12, on "Interpretation of Biochemical Findings in Urologic Disease."—Drs. George F. Gracey, Jacob Landis Zimmerman and Walter D. Hawkins presented a symposium on diseases of the upper respiratory tract at the meeting of the Dauphin County Medical Society, Harrisburg, March 6.—Dr. Harry M. Eberhard, Philadelphia, addressed the Harrisburg Academy of Medicine, March 20, on "What Has the Gastro-Enterologist Contributed to Medicine?"

Philadelphia

Packard Lecture—Dr. Anton J. Carlson, Chicago, delivered the annual Frederick A. Packard Memorial Lecture of the Philadelphia Pediatric Society, April 10, on "The Mechanism of Appetite, Hunger and Thirst."

Personal—Dr. Benjamin Franklin Stahl was the guest of honor at a reception given by the Philadelphia College of Pharmacy and Science, March 19, in honor of the fiftieth anniversary of his graduation from the school. President Wilmer Krusen presided and speakers included Drs. Alfred Stengel, William Pepper and Moses Beland. Dr. Stahl is a former president of the Philadelphia County Medical Society.

Annual Diphtheria Immunization Campaign—The Philadelphia County Medical Society is conducting its annual campaign for diphtheria immunization during April and May. Through the cooperation of the department of health, temporary distributing centers have been established to supply toxin-antitoxin free to physicians during this period. The health department refers to private physicians all patients who come to the health centers and who are able to pay. The society's commission on medical economics has suggested a form letter to be sent by physicians to their own patients urging that children be immunized. A recommendation adopted by the commission stated that members should be advised that it is not only ethical but also their duty to solicit their patients to present themselves for periodic health examinations and for immunizations and to cooperate with the department of public health in all matters of preventive medicine.

The Gross Prize in Surgery—The Philadelphia Academy of Surgery announces that essays will be received in competition for the Samuel D. Gross Prize until Jan. 1, 1935. This prize of \$1,500 is awarded every five years to the writer of the best original essay not exceeding 150 printed pages on some subject in surgical pathology or surgical practice founded on original investigations. Candidates must be American citizens. It is stipulated that the winner shall publish his essay in book form and that he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. The essay must be written in English by one author, typewritten, marked by a motto and accompanied by a sealed envelop bearing the same motto and containing the name and address of the writer. The committee reserves the right to make no award if no essay is considered worthy. Unsuccessful essays will be returned if claimed by the authors or their agents within a year. Manuscripts should be addressed to the Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, College of Physicians of Philadelphia, 19 South Twenty-Second Street, Philadelphia.

RHODE ISLAND

Bills Passed—The following bills have passed the Senate: S. 123, to repeal the laws relating to narcotic drugs and to enact the uniform narcotic drug act, and S. 177, to amend the medical practice act by proposing that in an appeal from an order of the board of medical examiners refusing to issue or revoking a license to practice medicine the Supreme Court may review the evidence presented before the board and may in its discretion affirm, overrule or modify the order of the board but the order shall remain in full force and effect during the pendency of the appeal.

SOUTH CAROLINA

Bill Enacted—S. 770, the uniform narcotic drug act, was approved by the governor, April 12.

Society News—Speakers at the annual meeting of the South Carolina Pediatric Society, Florence, January 30, were Drs. Joseph I. Waring, Charleston, on "The Newer Concept of Allergy," Alfred R. Shands Jr., Durham, N. C., "Minor

Orthopedic Conditions in Children", Olm B Chamberlain, Charleston, "Chorea and Habit Spasms," and Christopher Johnston, Durham, "Cardiac Diseases in Children"—Dr Julian P Price, Florence, was elected president of the South Carolina Pediatric Society in January

TENNESSEE

Society News—Drs Elliott P Joslin, Boston, and John S Coulter Chicago, addressed the Nashville Academy of Medicine, February 14, on diabetes and physical therapy in rehabilitation of the disabled, respectively—Dr Wallace S Duncan, Cleveland, was the speaker, March 20, on "Sacro-Iliac Disease—Its Etiology, Treatment and Review of End-Results"—Dr Hermon Hawkins, Jackson, presented a paper on diseases of the gallbladder before the Madison County Medical Society, February 7—Drs Lewis L Neblett, Clarks-ville and Paul W Wilson addressed the Montgomery County Medical Society, March 9, on "Treatment of Carbuncle" and "Laryngeal Diphtheria," respectively—Dr Carey O Foree, Athens, addressed the McMinn County Medical Society, Athens, March 8, on "Penetrating Wounds of the Chest"

TEXAS

Society News—Dr Willard Bartlett, St Louis, and W T Dawson, A M, Galveston, addressed the Galveston County Medical Society, Galveston, January 15, on "The Psychiatric Approach to Surgery" and "Atebrm in the Treatment of Malaria," respectively—The Ector-Midland-Martin-Howard Counties Medical Society at a meeting in Big Springs, January 12, voted to reorganize to include Andrews and Glasscock counties in a new society—Drs Everett C Fox, Dallas, and Judson T McRee, Longview, addressed the Gregg County Medical Society, Longview, February 8 on diagnosis and treatment of syphilis and acute surgical conditions in the abdomen, respectively—The Wilbarger County Medical Society was reorganized at a meeting in Vernon recently, with Drs Albert C Rogers and Harold Lindley, Vernon, as president and secretary, respectively

WISCONSIN

University News—Dr William Allen Pusey, professor emeritus of dermatology, University of Illinois College of Medicine, Chicago, gave the first annual Marquette University Memorial Lecture, February 22, at the school of medicine, on medicine and culture

Fund for Cancer Research—The University of Wisconsin has recently received a bequest of \$300,000 for the establishment of a cancer research center through the will of Miss Jennie Bowman, Wisconsin Dells, who died February 12. The university plans to extend studies carried on by Prof Michael I Guyer, Ph D, for the past eight years

GENERAL

National Academy of Sciences—The annual meeting of the National Academy of Sciences will be held in Washington D C, April 23-25, at the academy building. Among subjects of medical interest to be presented are the following

Dr Simon Flexner New York Source and Mode of Infection in Polymyositis

Drs Francis G Benedict and Howard F Root Boston Potentialities of Extreme Old Age

Drs Francis Peyton Rous and Joseph W Beard New York Neoplastic Traits of a Mammalian Growth Due to a Filtrable Virus—the Shope Rabbit Papilloma

Dr Eugene F Du Bois and James D Hardy New York Surface Temperature and Radiation of Heat from the Human Body

Warning Spurious Advertising Representatives—Certain unauthorized persons are operating in the East, particularly in New York City, and claiming to be duly accredited advertising representatives for publications of the American Medical Association. An executive of one firm has reported that one of these spurious representatives attempted to secure an advertising contract by high pressure methods and failing in this dropped the threat that the American Medical Association might bring some sort of pressure if he refused to go along. All such representations are false and business firms are hereby advised that any duly accredited advertising representative for the American Medical Association is prepared to show credentials. If unable to show credentials he should be regarded as an impostor

Pediatrics Journal Fifty Years Old—The *Archives of Pediatrics* celebrated the fiftieth anniversary of its founding in the February issue by reprinting articles published during the first year of its history. There are articles by Drs Abraham Jacob, William T Plant and J Lewis Smith clinical lec-

tures by Drs John M Keating, Frederick Forchheimer and Louis Starr, and clinical memoranda by the late Dr Luther Emmett Holt and Drs William P Northrup, New York, and Henry Dwight Chapin, Bronxville, N Y. Translations and abstracts of literature of fifty years ago are also included. The first issue of this journal, said to be the first in this country devoted exclusively to pediatrics, was dated Jan 15, 1884. The founder and first editor was Dr William Perry Watson, Jersey City

Medical Bills in Congress—Change in Status H R 7833, to provide revenue and equalize taxation, has passed the Senate, with amendments. One of the Senate amendments would impose an excise tax on the domestic processing of "imported fish oil (excepting cod and cod liver)." Bills Introduced H R 9069, introduced (by request) by Representative Celler, New York, provides for the establishment of unemployment and social insurance. The Secretary of Labor is authorized by the bill to provide for the establishment of social insurance for the purpose of paying workers and farmers insurance for loss of wages because of part-time work, sickness, accident, old age, or maternity. H R 9122, introduced by Representative Pierce, Oregon, provides for the sanitary inspection of the manufacture of oleomargarine and for taxation of oleomargarine containing foreign produced ingredients

News of Epidemics—Scarlet fever has been epidemic in Milwaukee for several weeks, 640 active cases were reported by the health department March 31. The city council granted a special emergency appropriation of \$15,000 to the health department, March 19, for a campaign of testing for susceptibility and of immunization in the schools. The Milwaukee County Medical Society is cooperating in the program—Forty-five men in Civilian Conservation Corps Camps in central New York were stricken with scarlet fever in March, there was one death. The epidemic was reported to be under control, March 20. It was reported that the infection was traced to impure milk—The Civilian Conservation Corps camp at Fort Hunt, near Washington, D C, was quarantined for the week preceding April 4, after two youths developed measles—The Danville State Hospital for Mental Diseases, Danville, Pa, was quarantined, March 27, when five cases of scarlet fever developed among patients and nurses

Society News—Dr Warren H Lewis, Baltimore, of the Carnegie Institution of Washington, D C, was elected president of the American Association of Anatomists at the annual meeting in Philadelphia, March 30. Vice presidents elected were Edmund V Cowdry, Ph D, St Louis and Bradley M Patten, Ph D, New York, Dr George W Corner, Rochester, N Y, was reelected secretary—Dr William Boyd, Winnipeg, Canada, was elected president of the American Association of Pathologists and Bacteriologists at the annual meeting in Toronto, March 29-30, and Dr Howard T Karsner, Cleveland secretary. The association will meet in New York, April 18-19 1935—Dr Samuel J Crowe, Baltimore, was elected president of the American Otological Society at the sixty-seventh annual meeting in Atlantic City, April 7. Dr Francis R Packard, Philadelphia, vice president, and Dr Thomas J Harris New York, reelected secretary—The theme of the annual convention of the Western Hospital Association in Sacramento, Calif, April 9-13 was "The New Era in Hospital Service." Speakers at various sessions included Rev Alphonse M Schvittalla, St Louis Michael Davis, Ph D, Dr Malcolm T MacEachern and Mr Paul Fesler, all of Chicago

Rural Health Conservation Contest—In cooperation with the American Public Health Association the U S Chamber of Commerce has announced an interchamber rural health conservation contest, to further the development of sound rural public health work in order that community health services may be improved. This is in addition to the interchamber health conservation contest for cities, which has been held annually for several years. The contest is open only to rural whole time counties or district health units and the county must be enrolled by the local chamber of commerce or similar organizations affiliated with the U S Chamber of Commerce. A fact-finding schedule, similar to that used in the city health conservation contest but which is adapted to rural areas, will form the basis for grading the counties or district health units. Advisory field services will be rendered to those enrolled counties or districts which request such services specifically. The interchamber rural health contest has been made possible through a grant by the W K Kellogg Foundation of Battle Creek, Mich. Information may be had from the insurance department of the U S Chamber of Commerce Washington D C or the committee on administrative practice American Public Health Association 450 Seventh Avenue, New York

March 24, 1934

Positions Open at the British Post-Graduate Medical School

The senate of the University of London has invited applications for four chairs tenable at the British Post-Graduate Medical School. They are the chair of medicine (salary \$12,500 a year), chair of surgery (salary \$12,500 a year), chair of obstetrics and gynecology (salary \$12,500 a year) and chair of pathology (salary \$10,000 a year). Applications (twelve copies) must be received not later than May 4. Candidates must possess qualifications registrable in Great Britain and their applications must be accompanied by the names of not more than three persons to whom reference may be made. Any referees resident abroad should be asked to write direct to the academic registrar. The holder of the chair will have the title of Professor in the University of London and Director of the Surgical (or other) Unit at the British Post-Graduate Hospital and Medical School. The chair will be a whole time appointment and the professor may not hold any other public appointment or engage in any other professional work without the approval of the governing body of the school. He is subject to an age limit of 60 years, with the proviso that on the advice of the governing body the appointment can be renewed until a later age. The professors will be required to organize a department of clinical research and do all in their power to promote the advance and study of their subjects.

Death from Treatment for Reducing Weight

An inquest has been held on the body of a young woman, a cabaret artist, who died while undergoing treatment to reduce her weight. This included steam baths, massage, radiant heat and Dekrysil capsules. The treatment was prescribed by a physician in the first instance but she afterward bought the capsules on her own account from a pharmacist. She bought a bottle of twenty-five on February 1 and another on February 20. She died on February 22. The pharmacist had received a warning from the manufacturers that the capsules should be taken under medical advice and he told the deceased so. Evidence was given by the chief chemist of "Crooke's Laboratories," the manufacturers of the capsules. He said that their purpose was to increase metabolism with a view to what was called slimming. They were put on the market in 1933 and the label on the bottle read "To be administered only on medical prescription." There was also issued with the capsules a leaflet stating that the effects should be carefully studied and that nausea or intolerance to the drug should lead to special investigation. The dosage was given as one capsule daily and it was added that if the metabolic rate was increased to more than 50 per cent the treatment should at once be stopped. It appeared that the deceased had taken as many as seventeen capsules since February 20, as only eight remained in the bottle found after death. In September 1933 the manufacturers suggested to the authorities that Dekrysil should be put on the Poisons List so that it could be bought only on a medical prescription. Dr. Roche Lynch, government analyst, stated that he had found traces of nitrophenol in the stomach and intestine. All drugs of the nitrophenol type were liver poisons, and he understood that they had only recently been used for slimming purposes. They were dangerous and should be under control. Death was due to taking an excessive quantity. So much fluid was exuded in the trachea and bronchi as to cause "internal drowning." The coroner said that modern

feminine fashion demanded a slim figure and that some women would do anything to attain it. But in this case the motive was not so much vanity as that the woman's employment as a dancer made it imperative that she should remain slim. In the first instance she sought medical advice and had she continued to follow it she might have been alive today. The proper way to cut down fat was by diet and exercise. The nitrophenol drugs were still in the experimental stage and dangerous even under skilled supervision.

The Pathology and Treatment of Asthma

The work of the Asthma Research Council has been reported in previous letters. One of the research clinics is maintained at Guy's Hospital under the supervision of Dr. A. F. Hurst and employs a team of physiologist, clinical pathologist, biochemist, radiologist and physician. Dr. A. F. Hurst, who is the physician, states in a paper contributed to *Guy's Hospital Gazette* that during 1933 there were 5,575 attendances at the clinic with about 450 new cases. In an analysis of 500 patients who passed through the clinic, Dr. Witts found two characteristics: (1) frequency of protein hypersensitiveness, as revealed by cutaneous reactions and in the personal and family history, (2) a high incidence of morbid changes in the upper and lower respiratory tract. But he does regard treatment directed to the respiratory tract as of much success. On the other hand, desensitizing treatment has not given encouraging results except in pollen asthma in which it is possible to ameliorate the symptoms in about two thirds of the cases and to give complete relief in about one third.

Dr. Hurst thus enumerates objections that might be raised to the view that the treatment of an allergic disease consists in discovering the substance to which the patient is hypersensitive and desensitizing him to it. 1. There are a multitude of potential allergens. Always there is the problem of asthma patients in whom no skin reactions can be demonstrated and the flora and fauna of the home and surroundings have to be searched over anew. 2. Multiple sensitization is present in two thirds of the patients. 3. The interpretation of skin tests is difficult. A patient may give positive reaction to substances which do not affect him clinically and negative reactions to those which do. Negative skin reactions are frequent in patients who are food sensitive. 4. Desensitization is difficult. 5. The morbid diathesis is persistent and new sensitization develops. In asthma, single sensitization is unusual, specific desensitization is arduous, and the relief from it is rarely more than transient. While the patient is being desensitized to one allergen, fresh sensitizations may develop. Protein sensitization is more widely diffused than has been appreciated, and the asthmatic person differs from many of his healthy fellows only in the severity of the manifestations. 6. The severest cases of asthma are often those in which there is the least evidence of protein sensitivity. 7. Asthma is relieved by epinephrine. Burn has suggested that the allergic state in general is not due to the presence of unusual substances in the blood but to deficiency in epinephrine. It is known that all skin reactions are difficult to obtain after injection of epinephrine. But Witts does not go so far as Burn and attribute the pathology of asthma entirely to biochemical or humoral defect. The etiology of disease is not always a single unit, and he suggests an external as well as an internal cause, analogous to the extrinsic and intrinsic factors in pernicious anemia.

The International Status of Science

Prof. A. V. Hill, the physiologist, delivered the Huxley Memorial Lecture, taking for his subject the International Status and Obligations of Science. Professor Hill said that science and learning have for several centuries been regarded by all civilized communities as entitling their followers to

immunity from persecution. Science was a common interest of mankind. It transcended the bounds of nationality. If science lost its intellectual honesty and political independence, if it became tied to emotion or the propagation of particular social or economic theories, it would cease to have its general appeal. The coercion of scientific people to certain specified political opinions, as in Russia, Germany or Italy, might lower the standard of scientific honesty. Scientific men and scholars had been persecuted or dismissed from Germany for reasons of race or for independence of opinion. If there was one single idea that by common consent represents the contribution of England to the common welfare of the world, that idea was freedom. The American commonwealth was founded by English people on the same idea. Professor Hill had wanted closer cooperation with Germany in science, but this was rendered impossible by her offending against the fundamental rule of freedom of thought and research. It might have seemed impossible that in a highly civilized country reasons of race, creed or opinion could lead to the drastic elimination of a large number of the most eminent men of science, many of them of the highest standing, good citizens, good human beings. Freedom itself was again at stake. Would man ultimately destroy in his folly all that he has built up? Professor Hill thinks that the only hope is the cooperation of intelligent people of good will in the various countries. The pterodactyl's achievements in aviation did not save it from extinction, it had some fundamental unfitness. Man's amazing achievements in controlling the forces of nature might be neutralized by domination of the intellect by the passions. Professor Hill thinks that the hope of the future lies in friendly rivalry and cooperation of Britain with the United States.

The New British Pharmaceutical Codex

In an address to the British Pharmaceutical Society, Mr. C. E. Corfield said that during recent years the Codex had proved of ever increasing value as a standard book of reference. The society formed a Codex revision committee in 1930 and throughout the revision it was borne in mind that the book was a work of reference for pharmacists and physicians, as well as one of standards and drugs not included in the British Pharmacopoeia. A feature of the new Codex was the inclusion of a series of requirements and tests under the heading of "Standard" which provided manufacturers and all engaged in the preparation of medicaments with a more uniform standard than had been available. The general index of drugs based mainly on their therapeutic uses, had been discontinued and replaced by a list based as far as possible on pharmacologic principles. The index of proprietary substances was an important feature. It contained many substances met in commerce or used in medicine only under proprietary names.

Native Physicians Trained in Fiji

At Suva, in Fiji, a central medical school has been established by the government under the control of British physicians, for the training of selected students as native medical practitioners for work in Fiji and the neighboring islands. The object is that they may carry out medical and health work in their own group of islands and thus not only bring medical help within the reach of a large number of their countrymen out of reach of other medical assistance but also by preventive measures raise the general standard of health throughout the islands. Graduate courses also are provided. The experiment has been quite successful. A monthly journal the *Native Medical Practitioner* is published by the school. The February issue contains useful and practical articles contributed by natives, such as 'A Case of Strangulated Inguinal Hernia (with successful operation in the remote island of Rotuma)' 'Intestinal Parasites Masquerading as Other Diseases (hookworm infestation is almost universal and roundworm general)

BERLIN

Feb 26, 1934

Promotion of Marriages in the New Reich

The new attitude toward marriage has been referred to in previous letters. Now that this subject has become clarified, it is interesting to learn the views of Professor Kuhn, hygienist of Giessen. In an address before the medical society of Frankfurt-on-Main, he emphasized that, in order to effect a eugenic transformation of the whole people, not only negative measures, such as the new sterilization law, are needed, but the most significant thing is to increase the birth rate and to preserve child life. Marriage consultation and marriage promotion are important aids. The individual physician is the natural center for marriage consultation, but there must be specialists for consultations pertaining to hereditary biology. The training received by a specialist in this field must be different from that of a general hygienist. The efforts to improve the hereditary qualities of the whole people will prove successful through the creation of chairs of race hygiene, as has recently been done in Berlin and Munich. The marriage consultation centers must be available for information concerning questions pertaining to future marriage and to sex relations, and, for married couples, concerning questions pertaining to married life.

The promotion of marriages has been accomplished in recent decades by advertisements in the press and by commercial marriage bureaus, whose activities are looked at askance by many persons. For the development of a people on a eugenic basis however, it is proper that persons wishing to marry be aided in the search for a mate. Centers must be created that will aid truly German citizens to find a life partner. In German Southwest Africa there was a consultation center before the World War. The ladies' aid of the deutsche Kolonialgesellschaft sent thousands of girls to Southwest Africa during the years 1898-1914, to become the wives of German farmers. During the World War there was an official marriage promotion center in Magdeburg. Such organizations will, in the future be entrusted to the bureaus of health, which have to deal also with questions of race hygiene.

The new trend has its effect on marriage. An increased willingness to marry has been observed. In the fifty-one German cities of more than 100,000 population, 15 per cent more marriages took place in July 1933, 30 per cent more in August, and 53 per cent more in September, than in the corresponding months of 1932. In November there were 19,805 marriages, or 41 per cent more than in November 1932, and in December 25,900 or 50 per cent more than in the corresponding month of the previous year. For the year 1933 about 40,000 more marriages were contracted (208,700 as against 168,655 in 1932), the main increase having been in the second half year, or after the law for the furtherance of marriages went into effect. The year 1933 brought, in the large cities of Germany, the largest number of marriages since the postwar years 1919-1922. There is no doubt that this gratifying increase is due chiefly to the loans to married couples, although the readjustment process that has taken place, whereby an endeavor has been made to supply work for as many men as possible and thus to facilitate marriage for the women who lose their positions has played a part.

The government loans for the furtherance of marriages and for the elimination of women from the labor market have led to interesting results. The finance ministry had counted on granting 20,000 such loans per month, but the demand has exceeded expectations. During the first six months (August 1933 to January 1934) 183,000 loans were granted, which constituted an average of 30,500 per month. The special tax imposed on single persons does not cover the cost of this legislation. The federal finance ministry has decided to sus-

pend the granting of marriage loans until March 31, 1934. During the following twelve months no more than 250,000 new loans are to be granted. The finance minister is endeavoring to induce employers to grant marriage benefits to women who give up their positions, and, in return for such benefits, he promises relief from taxes. Recent statistics on intermarriage between members of various religious bodies do not completely bring out racial distinctions. A recent report of the federal bureau of statistics shows that there were in 1931, in a total of 515,403 marriages, 83,014 (16 per cent) marriages between persons of different faiths. The percentage of such intermarriages has been constantly increasing since 1920. The major portion of these mixed marriages were entered into by a Protestant and a Catholic (75 per cent). The number of members of Evangelical bodies united in marriage with members of various other Christian sects was 1,732 (2 per cent), with Jews, 891 (1 per cent) and with persons professing no religious faith, 17,247 (22 per cent). The percentage in 1905 of marriages between Protestants and persons making no religious professions was 0.11 and in 1928 was 20. Since 1928 the increase has been slower. These figures concern civil marriages. The mixed marriages with church weddings present a different picture. Weddings were held in the Evangelical church in 1925 in 34 per cent of all mixed marriages, and in 1931 in 28 per cent.

Since August 1933 there has been an increase in the birth rate of the large cities. In the third quarter of 1933 the decline in the birth rate in Prussia was brought to a halt. The increase in the birth rate, it is assumed in official quarters, is due to a great extent to the fact that criminal abortion has been greatly checked. The year 1933, as a whole showed a birth rate of 10.9 per thousand of population or 0.1 per thousand more than in 1932. The city of Berlin is resorting to many new measures to lift the birth rate. One new measure adopted is for the city to serve as godmother to all children born within its boundaries. The care of godchildren is to be extended over a period of years and will be continued if the family is for any reason compelled to change its residence (within Germany).

Reintroduction of Titles

When the German republic was established, all titles and orders, at least so far as any special honors were concerned were abolished. Now a decree of the president of the republic, dated January 30, provides that "for special services promoting the welfare of the people and state" titles may be bestowed on officials and members of the liberal professions. Such honors will be conferred solely on persons who at all times are ready and eager to support the national state. Few titles, however, are to be conferred. It has been arranged that the title of "geheimer rat" may be bestowed on professors in government universities and directors of government scientific institutes. Furthermore persons devoting themselves to the liberal sciences and arts may, as a reward for special merit, receive the title of professor, and persons devoting themselves to liberal medicine (or to veterinary science) may be given such titles as "sanitätsrat" and "geheimer sanitätsrat".

Reorganization of the Society of Psychotherapy

After Professor Kretschmer, as a result of the great political upheaval in Germany, had resigned from the chairmanship of the Allgemeine ärztliche Gesellschaft für Psychotherapie and from the management of the *Zentralblatt für Psychotherapie* fundamental changes were brought about. The chairmanship of this international society was taken over by Dr. C. G. Jung of Küsnacht-Zürich. Also a German Allgemeine ärztliche Gesellschaft für Psychotherapie has been created as a chapter on the basis of the "leader principle," as approved by the new

German government. The new society is under the leadership of Professor Goring of Eberfeld. The society plans to publish special numbers of the *Zentralblatt*. The German society has received the commission, by the holding of consultations, addresses and lectures, to mold the thoughts of the nation on scientific and psychotherapeutic lines. The two societies are independent of each other but cooperate. The secretary, Dr. W. Cimbal of Altona, states that the separation of the two societies seemed to be the only possible way to develop psychotherapy in a uniformly scientific and practical manner. The mutual relations of the German and the international society will be worked out in detail at the psychotherapeutic congress in Nauheim in April. As the editor of the *Zentralblatt* states, "The congress will serve to develop a Germanic system of psychiatry and psychotherapeutics." Also the new editor of the *Zentralblatt für Psychotherapie*, Dr. C. G. Jung, says, "The widely different conceptions of the Germanic and Jewish psychology, of which persons of insight have long since been aware, will no longer contend with each other, which will certainly advance the cause of science."

The Plight of the Midwives

A decree of the Prussian minister of the interior and observations of the newly founded Aufklärungsamt für Bevölkerungspolitik und Rassenpflege give evidence that the midwife service in Germany is not fully appreciated. Furthermore, owing to the decline in the birth rate and the abolition of some provisions of the Prussian law pertaining to midwives, the profession of midwifery has suffered impairment. Many midwives are no longer in a position to provide the necessary aids for the practice of their profession and their continued professional training. Although the law requires them to respond to every call, they have no assurance that they will be paid for their services, owing to the reduced financial status of portions of the population. The midwives are often so poor that they are not able to pay their dues for old age insurance. Every endeavor must be put forth to reestablish the midwife service on a solid footing. Otherwise there is a danger that mothers will not receive proper care during childbirth.

ITALY

(From Our Regular Correspondent)

Jan 31, 1934

National Congress of Urology

The Società Italiana di Urologia held its twelfth national congress in Pavia, under the chairmanship of Prof. U. Gardini. The chief topic was endoscopic treatment of hypertrophy of the prostate. The subject was treated under two heads, the official paper on the first being assigned to Professor Caporale of Turin, and the second to Professor Bonanome of Rome.

Caporale recalled that for the treatment of obstructions preventing the normal flow of urine many methods, surgical and conservative, have been proposed. Among the former, prostatectomy during the past thirty years has won the favor of surgeons and has brought relief to a great number of patients. Today there is a tendency to replace total removal of the prostate with partial prostatectomy, for which many methods and instruments have been proposed. The speaker had studied 597 cases of partial interventions—supplied, in part, by Italian or foreign colleagues—and had found that the greater part of the patients were treated with electrocoagulation. The remainder of the patients were subjected to electroresection, with various types of apparatus. To his own patients, the speaker applied resection with the resectoscope or the electrotome, or diathermocoagulation. The technic must be precise if satisfactory results are to be secured. Great importance attaches to the generator of the current. In establishing the indications, one must take account, in addition to the general and local clinical

examination the age of the patient and the urethral and rectal exploration and not rely solely on the urethrocystoscopic examination. The preoperative medical treatment to apply in case of partial prostatectomy is the same as that used in the total operation. A complete anesthesia is the principal factor of success. The most used forms are epidural, rachianesthesia, local urethral and vesical and prostatic, general anesthesia being reserved for special cases. The postoperative treatment must be meticulous, as in a major operation. The complications are chiefly hemorrhage and infection. The latter is frequent in endoscopic interventions and develops mainly in the urinary organs. In the cases studied by the speaker, pyuria occurred in all the patients, in a few cases there was orchiepididymitis or phlebitis. The speaker did not encounter either retention or incontinence of the urine. He concluded that endoscopic interventions in disorders of the neck of the bladder and of the prostate should be assigned an important place in urologic practice, although he would not contend that prostatectomy should be entirely abandoned.

Professor Bonanome spoke on the transurethral treatment of obstructions of the neck of the bladder, describing the instruments used and the more important methods employed. The speaker is an advocate of the modern instruments for resection and expressed his preference for the McCarthy and the Kirwin types, the former for resection in an anteroposterior direction and the latter for use in a rotatory direction. The endoscopic method is a welcome addition, particularly in the application of electric surgery, but at present it cannot replace the surgical operations, for the same dangers are involved. It cannot be performed ambulatorily. It is not true that endoscopic treatment should be applied only to patients who, owing to the unpaired condition of the kidneys and heart, cannot be subjected to a surgical operation. One should be distrustful of such patients, for their already unstable equilibrium may easily be disturbed.

Chaudano reached the conclusion that, for prostates of average size, the only feasible intervention is prostatectomy.

Luis of Paris, who was the first surgeon in Europe to apply endoscopic resection of the prostate by the natural routes under sight control, communicated the results of his experience. With his method of perforating the prostate in a series of 299 interventions he observed 80.4 per cent of excellent results and 19.6 of incomplete results.

Lasio of Milan concluded that endoscopic treatment of hypertrophy of the prostate cannot compete, as yet, with the surgical methods.

Nisio of Bari emphasized the value of diathermocoagulation in disorders of the neck of the bladder. With respect to hypertrophy of the prostate, he thinks that the resector and the associated instruments do not constitute a suitable method.

Rome was chosen as the place of meeting for the next session, in October 1934. The chief topic on the program will be "Study on Renal Functioning in Connection with Urinary Surgery."

Enrico Burci

The death of Prof. Enrico Burci, occupant of the chair of clinical surgery at the University of Florence, is announced. He graduated at Pisa in 1885 and in 1899 he received a call to the Clinica chirurgica of Padua. In 1903 he removed to the Clinica chirurgica in Florence. He was the author of 127 publications on various subjects of surgery. His chief merit was the transformation, a number of years ago, of his institute into a surgical polyclinic in which he surrounded himself with assistants who were specialists. As a result the students secured a complete instruction in the various specialties. His pupils occupy at present five chairs of general clinical surgery. Three others hold other chairs. Many are directors of important surgical departments in foreign and Italian hospitals.

During the war he served with the rank of "generale medico." A former pupil, Prof. Domenico Taddei, clinical surgeon in Pisa, has been called as his successor.

Center for the Treatment of Sterility

A center for the treatment of sterility was recently established at Turin, and the example will doubtless be followed by other cities. The center is located at the Clinica ostetrico-ginecologica universitaria. It is the first institute of the kind to be organized in Italy and consists essentially of an ambulatorium for the rendering of advice to sterile couples. The center will provide gratuitously for medication for actinic or diathermic treatment and for surgical interventions when needed. By means of frequent visits the effects of the treatment will be controlled. The institute is subsidized by the University of Turin and by the Clinica ginecologica.

March 6 1934

Vaccination Against Exanthematic Typhus Fever

The Charkov Bacteriologic State Institute has finished a study of antityphus vaccine. Experiments have shown that guinea-pigs, after they have been inoculated with the vaccine are immune to infection with typhus blood. Experiments were made on men who had never had exanthematic typhus. They were injected subcutaneously with brain tissue from guinea-pig, experimentally infected with typhus after the third and eighth passage. A reaction was observed in only two cases. In one case a typical picture was obtained of typhus after a period of eight days. Some other experiments with guinea-pig virus produced a typical form of typhus. Not one person who was inoculated first with experimental virus and later with blood from typhus patients became ill. The experimental virus produces in man an immunity to typhus. The next series of persons received subcutaneously killed experimental virus. No reactions were noticed. After a period of three and one-half months this series of men was inoculated with the blood of a typhus patient on the sixth day of the disease. Only one man from this group became ill, and he had a light form of typhus. At present these vaccinations are widely used. Further experiments on large numbers of men are planned, and after this the preparation of antityphus vaccine will proceed.

The Fourth International Congress on Rheumatism

The third International Antirheumatic Congress took place in Paris in 1932. The next congress will take place in Moscow in May of this year. About 200 scientists from twenty-three countries are expected to take part. The following subjects will be discussed: 1. Acute joint rheumatism. 2. Spa methods of treating rheumatism. 3. The rheumatism of workers in metallurgic plants.

Work preliminary to the congress is now in progress. In many towns committees have arranged clinics and conferences with specialists and general practitioners. A conference was held at Moscow, December 25-29, at which many papers were read.

New Sources of Vitamin C

The vitamin department under the guidance of Prof. B. A. Lavrov of the Institute of Communal Nourishment at Moscow has finished a series of experiments on the sources of vitamin C which was found in sorrel, black current and pine wood. The institute is preparing jam, preserves and liquors from pine wood. These products have practical value as prophylactic measures to prevent scurvy in the northern regions of Russia and in arctic expeditions. The irradiation of yeasts with ultraviolet rays from quartz lamps markedly increases their activity, making yeast much more effective than cod liver oil.

Feb 15, 1934

Cancer Research in Brazil

The wealthy Guinle family has created the "Foundation Oswaldo Cruz Against Cancer" and a large building for this work has been under construction for four years.

Dr Carlos Botelho Jr, originator of the Botelho test for the serodagnosis of cancer, has for eight years been studying the problem of treatment of cancer. He began his investigations in Paris, where he succeeded in transmitting to horses malignant tumors of man by means of a special technique. He thus was enabled to obtain a serum that was used with favorable results in many cancer patients at the Hotel-Dieu. Three years ago Dr Botelho came to Brazil and established at his own expense the "Botelho Institute of Cancer" in São Paulo, where he was to pursue his studies. He developed a product with which cancer in animals was successfully treated. On the basis of results obtained in animals, Dr Botelho decided to extend his investigations to man and he was invited to continue his study in Rio de Janeiro, where a wealthy citizen, Dr Guilherme Guinle, constructed a pavilion in the Hospital of the Foundation Gaffree-Guinle, exclusively for Dr Botelho's study and investigation of cancer. This institute has been functioning now six months with regularity. It is completely equipped for its purpose and is divided in two sections: scientific research laboratory and a clinic and dispensaries.

Dr Botelho and his collaborators have published nothing as yet from the institute, but the results obtained have already been heard abroad and they offer encouragement in the campaign against this scourge.

Research on Alastrim

Dr Henrique de Aragão, chief of service of the Oswaldo Cruz Institute, who has for years made microbiologic studies on smallpox and alastrim, has made an interesting report on his investigations. He has had occasion to study the virus of alastrim in lesions produced in *Macacus rhesus* inoculated intravenously with pus from the pustules of man. Some rhesus monkeys inoculated intravenously and intradermally have presented characteristic eruptions. The examination of slides made from material in the pustules on inoculated macacus monkeys has revealed large numbers of the elementary corpuscles of alastrim like those previously observed and described by the author in human cases. They are small, round corpuscles, are numerous, and stain well by Loeffler's or any other analogous method. This once more confirms the opinion of the author expressed previously that these corpuscles are in reality the virus of alastrim and the causal agent of this disease of the smallpox group, to which he has given the name *Chlamydozoon ribasi*.

Ten cases of alastrim in a recent small epidemic at Rio presented the opportunity to study the virus. These ten patients had pustules in different stages of evolution. Examination of the pus once more confirmed the fact that the bacteria that infect these pustules coincidentally with the virus are *Staphylococcus aureus* and albus, contrary to what occurs in smallpox, in which the prevalent microbe in the pustules is the streptococcus. In alastrim this microbe was found by the author in only three cases from among dozens that he had seen. Thus a differentiation is established between alastrim and smallpox through the bacterial flora existing in the pustules.

An International Leprosy Center Established

An international leprosy center will be established this month in this city under the auspices of the League of Nations. There are almost 300,000 lepers in the world, according to calculations

based on an official census. Argentina has less than 8,000 lepers, while India has more than 102,000.

At a meeting in Geneva it was decided to nominate as director of the center Prof Carlos Chagas of Brazil and to permit him to remain also as director of the Instituto Oswaldo Cruz. The center will undertake any work that may contribute to the prevention of leprosy, taking especially into account its treatment. Scientists and hygienists of various countries will be invited to take a course of instruction and to promote cooperation in a campaign against the disease. Mr Guilherme Guinle and the Brazilian government will each pay 50,000 Swiss francs annually for ten years to defray the expenses of the center, or a total amount of 300 millions of Brazilian paper reis. The league has announced that it is ready to send specialists in leprology to Rio de Janeiro and to pay their traveling and maintenance expenses, which will approximate 50,000 francs a year. The offer to install the international center came from the Brazilian government, which wrote to this effect to the council of the league, April 15, 1931. The sanitary organization of the league has described Brazil as one of the most advanced countries as regards the campaign against leprosy. The governing body of the leprosy center includes Sir George Buchanan, Surg-Gen H. S. Cumming, Prof Ricardo Jorge, Mrs Janet Campbell, Dr J. J. Jotta, Prof A. Lutrario, Prof Leon Bernard and Professor Bastianelli. The commission of administration includes seven members under the presidency of Mr Guinle, with Prof E. Burnet representing Mr Avenol, general secretary of the League of Nations. The commission suggests that the sanitary organization of the league obtain the greatest possible cooperation from other South American countries in the campaign against leprosy.

Public Hospitals

The corner stones of the polyclinic hospitals of Gavea and of Villa Isabel were laid some days ago with appropriate ceremony. The hospital of Gavea on Mario Ribeiro Street will contain 500 beds and an outpatient service, which will serve not only the ward of Gavea but also the wards of Leblon, Botafogo and Copacabana. The Villa Isabel Hospital will be situated on the grounds of João Alfredo Institute. It will serve the wards of Andaraí and Tijuca and the center of the city until the completion of the Central Hospital on the Place of the Republic.

Marriages

WALTER THOMAS VANDAMET, Bloomington, Ind., to Miss Audrey Wettergren of Jeffersonville, recently.

JOHN RUSSELL MARTIN, Scottsboro, Ala., to Miss Elizabeth Ferrell of Memphis, Tenn., February 5.

HOMER WOOLERY to Mrs Maude Hughes, both of Bloomington, Ind., in Columbus, February 17.

SIDNEY E. STOUT, Fort Worth, Texas, to Miss Helene Earldine Robb of Pampa, February 14.

ADRIAN VAN DYKE HAGAMAN to Miss Sue Griffith, both of Jackson, Miss., in February.

SAMUEL SIMON ALTSZULAR to Miss Constance Wemberger, both of Detroit, March 4.

CARL JOHN GLASPEL to Miss Violet Mohagen, both of Grafton, N. D., recently.

JAMES H. BYRAM to Miss Elizabeth Patterson, both of Atlanta, Ga., March 17.

EUGENE E. SMITH, Waterloo, Iowa, to Miss Betty Groeger of Omaha, February 7.

MARLIN LESTER PURDIN, West Union, Ohio, to Miss Ruth Davidson, January 31.

JOHN W. PARSONS to Miss Isabella G. Hunner, both of Baltimore, March 17.

Deaths

Charles Dewey Center @ Quincy, Ill., Rush Medical College, Chicago, 1894, president elect of the Illinois State Medical Society, past president of the Adams County Medical Society, fellow of the American College of Surgeons, served during the World War, attending surgeon to the Blessing Hospital, aged 64, died, March 31, of a skull fracture received when he was struck by an automobile

Robert C J Meyer, Moline, Ill., Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1891, Rush Medical College, Chicago, 1892, at one time county coroner, and justice of the peace of Coe Township formerly secretary of the staff of St Anthony's Hospital, Rock Island, aged 68, died, March 4, of pyonephrosis

Don De Witt Knapp, Flint Mich., University of Michigan Medical School, Ann Arbor, 1906, member of the Michigan State Medical Society, past president of the Genesee County Medical Society, formerly health officer of Flint, on the staff of the Hurley Hospital, aged 52, died, March 19, of heart disease

John Sabert Mott, Kansas City, Mo., University of Michigan Medical School, Ann Arbor, 1867, an Affiliate Fellow of the American Medical Association, member of the American Academy of Ophthalmology and Oto-Laryngology, Civil War veteran, aged 89, died, January 7, of acute dilatation of the heart

William Harrison Weirich, Jacksonville, Ill., Bennett Medical College, Chicago, 1909, member of the Illinois State Medical Society, served during the World War, aged 48, on the staff of Our Savior's Hospital, where he died, March 17, of meningitis, following an operation for mastoiditis

Harry Aldes, St Paul, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912, member of the Minnesota State Medical Association, aged 50, on the staff of the Bethesda Hospital, where he died, March 21, of acute cholecystitis and hepatitis

William Daniel Atkins, Holdenville, Okla., Vanderbilt University School of Medicine, Nashville, Tenn., 1903, member of the Oklahoma State Medical Association, for many years health officer of Hughes County and Holdenville, aged 59, died, March 15, of cerebral hemorrhage

William Henry Aten @ Brooklyn, Long Island College Hospital, Brooklyn 1883, on the staffs of the Carson C Peck Memorial Hospital, Prospect Heights Hospital, Cumberland Hospital and the Brooklyn Nursery and Infants Hospital, aged 72, died, March 27, of heart disease

Jesse Fred Bond, St Louis, St Louis University School of Medicine, 1912, veteran of the Spanish-American War, formerly on the staff of the Alexian Brothers' Hospital, aged 53, died, March 14, in the Veterans' Administration Facility, Jefferson Barracks, of gastric ulcer

Dilver E Douglas @ Greensburg, Ind., Kentucky School of Medicine, Louisville, 1897, on the staff of the Odd Fellows Home Hospital, formerly member of the state legislature, for many years secretary of the city board of health, aged 63, died March 5, of heart disease

Francis Clark Penoyar @ South Haven, Mich., University of Michigan Medical School, Ann Arbor, 1903, past president of the Kalamazoo Academy of Medicine part owner of the Penoyar Memorial Hospital, aged 63, died suddenly, March 13, of coronary thrombosis

George S Wattam, Warren, Minn., Victoria University Medical Department, Coburg, Ont., Canada 1884, member of the Minnesota State Medical Association past president of the Northern Minnesota Medical Association, aged 77, died, March 17, of heart disease

George D Grant, Springfield, Ohio, Pulte Medical College, Cincinnati, 1878, member of the Ohio State Medical Association, for two years member of the board of education, aged 77, died, March 6, at the City Hospital of hypertrophy of the prostate

Robert Moses Clark, New Britain, Conn., University of Pennsylvania School of Medicine, Philadelphia 1891 member of the Connecticut State Medical Society, aged 63, died Dec 5 1933, in the Masonic Home, Wallingford, of cerebral hemorrhage

William Frederick Manuel, Pasadena, Calif., Harvard University Medical School, Boston, 1921, aged 39, died March 1, in St Vincent's Hospital Los Angeles, of subdural

phragmatic abscess and empyema following gastric resection for peptic ulcer

Amos William Shelley, Port Royal Pa., Bellevue Hospital Medical College, New York, 1874, member of the Medical Society of the State of Pennsylvania president of the Juniata County Medical Society, bank president, aged 83, died, March 1, of influenza

Charles Orin W Bartine, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1903, formerly public school physician for the city board of health, served during the World War, aged 54, died, March 8, of heart disease

Frank Amenzo Walters, Wisconsin Veterans Home, Wis., Hahnemann Medical College and Hospital, Chicago 1890 formerly mayor of Stevens Point, served during the World War, aged 69, died, January 30, of a self-inflicted bullet wound

James Wofford Sanders, New Iberia, La., Tulane University of Louisiana Medical Department, New Orleans, 1899, member of the Louisiana State Medical Society, aged 57, died, January 14, of cerebral hemorrhage and hypertension

Alonzo Slat Tredwell, Brooklyn, Long Island College Hospital, Brooklyn, 1893, member of the Medical Society of the State of New York, aged 65, died, March 8, in the Doctors Hospital, New York, of carcinoma of the esophagus

Berlie Wesley Mercer, Tiffin, Ohio, Eclectic Medical Institute, Cincinnati, 1897, member of the Ohio State Medical Association, on the staff of the Mercy Hospital, aged 68, died suddenly, March 9, of cerebral hemorrhage

Allen Franklin Mowery, Ashland, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1886, aged 75, died, February 27, of arteriosclerosis and chronic myocarditis

George Edward Gerken, Toledo, Ohio, University of Michigan Medical School, Ann Arbor, 1921, county jail physician, aged 37, died, February 26, in St Vincent's Hospital, of peritonitis, following an operation

Allen Joseph Fox, Norwood, Ohio, Eclectic Medical College, Cincinnati, 1917, served during the World War, aged 47, died, February 17, in the Bethesda Hospital, Cincinnati, of myocarditis and Hodgkin's disease

Edward Beecher Finck, Philadelphia University of Pennsylvania School of Medicine, Philadelphia, 1903 member of the Medical Society of the State of Pennsylvania, aged 77, died, March 24, of heart disease

Clinton J Hancock, Greenup, Ill., Medical College of Ohio, Cincinnati, 1897, member of the Illinois State Medical Society, aged 67, died suddenly, March 17, in a hospital at Effingham, of heart disease

Joseph Dunsmore Monteith, Stratford, Ont., Canada, Trinity Medical College, Toronto, 1895, member of the board of education of Stratford for eight years, formerly mayor, aged 68, died, January 8

William M Hilton, San Francisco, State University of Iowa College of Medicine, Iowa City, 1873, aged 86, died, January 11 in San Fernando, of chronic nephritis and hypertrophy of the prostate

William Clarence Matthews, Roswell, N M., National University of Arts and Sciences Medical Department, 1913 served during the World War, aged 59, died, suddenly, March 6, of angina pectoris

William E Herrin, Dallas, Texas (licensed in Texas, under the Act of 1907) member of the State Medical Association of Texas, aged 60, died, March 7, of carcinoma of the base of the tongue

Ernest F Crummer, Essexville, Mich., Detroit College of Medicine, 1894, village president for four years and postmaster for sixteen years, aged 67, died suddenly, March 10 of cerebral hemorrhage

Elias Sterling Cooper, Los Angeles, Jefferson Medical College of Philadelphia, 1877, Bellevue Hospital Medical College, New York, 1883, aged 81, died, February 12, of cerebral hemorrhage

James Riley Swisher, Healdsburg, Calif., University of California Medical Department, 1877 member of the California Medical Association, aged 84, died, January 31 of chronic myocarditis

Floyd Percy Brockett, Palmdale, Calif., Kansas Medical College, Medical Department of Washburn College, Topeka, 1906, aged 53, died, January 7, in Lancaster, of lobar pneumonia

Charles Edwin Park ⊕ New Haven, Conn., Yale University School of Medicine, New Haven 1881, aged 76, died, March 19, in the Hospital of St. Raphael, of carcinoma of the rectum

Cyril Justin Marshall ⊕ Orlando, Fla., University of Nashville (Tenn.) Medical Department, 1907, aged 51, died February 19, at his home in Sanford, of a self-inflicted bullet wound

Raschid S. Baddour ⊕ Brooklyn American University of Beirut School of Medicine, Beirut, Lebanon, Syria, 1893, aged 68, died, March 1, of arteriosclerosis and cerebral hemorrhage

Daniel Simpson Hager, Los Angeles, Bennett College of Eclectic Medicine and Surgery Chicago 1898 Rush Medical College, Chicago, 1900, aged 70, died, March 15, of pneumonia

Isaac M. George, El Dorado, Ark., Arkansas Industrial University Medical Department, 1896, aged 73, died, March 3, in the Warner-Brown Hospital, of acute nephritis and sclerosis

Curtis Nelson ⊕ Barrington, Ill., Rush Medical College Chicago, 1928, aged 31, died, March 2, when he fell from a fifth story window of the Presbyterian Hospital, Chicago

John Darling Churchill ⊕ Plymouth, Mass. Harvard University Medical School, Boston, 1900, aged 59, died March 2, in the Jordan Hospital, of uremia and acute nephritis

Carleton Yates Ford, Montreal, Que., Canada, Queen's University Faculty of Medicine Kingston Ont., 1900, served during the World War, aged 57, died, February 19

Bert Haughwout, Derry, Pa., Medico-Chirurgical College of Philadelphia, 1893, member of the Medical Society of the State of Pennsylvania, aged 66, died January 26

William Austin Schooley, Waldron Ind. Medical College of Ohio, Cincinnati, 1888, aged 68, died, March 7, of cerebral hemorrhage and hypostatic pneumonia

Ira Jacob Mizer ⊕ Columbus Ohio Ohio Medical University, Columbus, 1902, aged 60, died, March 12, in the White Cross Hospital, of heart disease

Henry Artelt, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1897, aged 65, died March 10, of carcinoma of the throat and tongue

Henry John Hollison, Carmel Calif. Herms Medical College, Chicago, 1906, aged 59, died, January 1, of pyonephrosis and transverse myelitis

Clarence Watson Mercer, Dillonville Ohio Starling Medical College, Columbus, 1891, also a druggist, aged 64, died, March 10, of heart disease

Franklin P. H. Akers, Collegepark Ga. Jefferson Medical College of Philadelphia, 1876, aged 81, died, March 25, of myocarditis and hypertension

John Thomas Binkley, San Diego Calif. Medical College of Ohio, Cincinnati, 1883, aged 70, died March 8, of angina pectoris and arteriosclerosis

John Frederick Moore ⊕ New York Bellevue Hospital Medical College, New York, 1888, aged 67, died suddenly, March 12, of heart disease

Albert D. Edwards, Walkertown N. C. University of Maryland School of Medicine, Baltimore 1903, aged 56, died, February 15, of pneumonia

John Clark Michaux, McMinnville Ore. Kentucky School of Medicine, Louisville, 1889, aged 76, died January 14, of cerebral hemorrhage

William Dennis Colby, Kansas City, Mo. Missouri Medical College, St. Louis, 1890, aged 72, died, January 16, of cardiac hypertrophy

Calvin F. Heffington, Havana Ark. Eclectic Medical Institute, Cincinnati, 1891, aged 82, died February 27, of heart disease

Neal McLain Draper, St. Louis St. Louis University School of Medicine, 1903, aged 58, died, March 5, of mitral insufficiency

Charles Lucian Kreeger, Kansas City, Mo. Kansas City Medical College, 1894, aged 63, died January 8, of angina pectoris

Charles E. Hubbard, Fayette Ohio Detroit College of Medicine, 1893, aged 64, was found dead March 12, of heart disease

Leonard Oscar Hayes, Fremont N. C. University College of Medicine Richmond, Va. 1897, aged 62, died, January 26

Charles D. Potts, St. Louis St. Louis College of Physicians and Surgeons 1892, aged 63, died February 19, of heart disease

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[Editorial Note The abstracts that follow are given in the briefest possible form (1) The name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Acetphenine Tablets—Llewellyn Laboratories Inc., Philadelphia. Composition Aspirin and caffeine. False statement of composition—[N J 20394 December 1933]

Adlum Active Radium Ointment—Adlum Products Inc. Battle Creek, Mich. Composition Essentially petrolatum and powdered mineral matter with negligible trace of radium. For pimples, ulcers, ringworm, piles, etc. False statements of composition, fraudulent therapeutic claims—[N J 20732 February 1934]

Asthmans—Philadelphia Capsule Company and Joseph McManus Philadelphia. Composition Minute quantities of calcium iodide and caffeine citrate. For asthma, whooping cough, etc. False claims for composition—[N J 20748 February 1934]

Bis Ma Cal—Llewellyn Laboratories Inc. Philadelphia. Composition Magnesium carbonate, bismuth subnitrate, calcium carbonate. False claims for composition—[N J 20394 December 1933]

Collins Plasters—John on & Johnson New Brunswick N. J. Composition Capsicum oleoresin, starch and rubber spread on cloth fabric attached to two metal strips, one of zinc, the other of copper. For relief of pain, inflammation, rheumatism, lumbago, etc. Fraudulent therapeutic claims—[N J 20100 December 1933]

Cyslittans—Philadelphia Capsule Company and Joseph McManus Philadelphia. Composition Tormin for cystitis, prostatic irritation, etc. Fraudulent therapeutic claims—[N J 20748 February 1934]

Dalgerine—Philadelphia Capsule Company and Joseph McManus Philadelphia. Composition Aspirin and acetphenetidin. For influenza, rheumatism, etc. False statement of composition, fraudulent therapeutic claims—[N J 20748 February 1934]

Ergot Anol—Cermak Drug Company, Bayonne N. J. Composition Essentially material derived from plants including in oil such as opium and one such as saffron. Contains no ergot alkaloids. For amenorrhea, dysmenorrhea, menstrual disorders, etc. Fraudulent therapeutic claims—[N J 20351 December 1933]

Frick's Eez All—Adolph F. Frick, San Francisco. Composition Alcohol 16 per cent, plant extracts and water. For pimples, boils, carbuncles, eczema, dandruff, psoriasis, rheumatism, gonorrhea, etc. Fraudulent therapeutic claims—[N J 20700 February 1934]

Hale's Household Pills—Kenyon & Thomas Company, Adams N. J. Composition Irritative drugs such as aloes, podophyllum and anise. For liver complaint, etc. Fraudulent therapeutic claims—[N J 20339 February, 1934]

Healthagain—Healthagain Laboratories Inc. Wellsburg W. Va. Composition Epsom salts, laxative drugs such as jalap, senna and rhubarb, sugar, alcohol and water. For high blood pressure, diseases of the liver, anemias, rheumatism, etc. Fraudulent therapeutic claims—[N J 20734 February 1934]

Hutchinson's Big Head Liniment—Hutchinson Medicine Company, Texarkana Texas. Composition Essentially kerosene oil of turpentine and trace of bicloride of mercury. For rheumatism, sciatica, lumbago, etc. Fraudulent therapeutic claims—[N J 20740, February 1934]

Hydrophn—Bika Biochemical Laboratories Philadelphia. Composition Tablets of milk sugar, organic nitrogenous material, plant material, calcium phosphate, traces of potassium, sodium, iron and manganese chlorides and sulphates. For dropsy, pericarditis, peritonitis, etc. Fraudulent therapeutic claims—[N J 20741 February 1934]

Kalmolax—Llewellyn Laboratories Inc. Philadelphia. Composition Phenolphthalein. False statement of composition—[N J 20394 December 1933]

Kemozone—Select Drug Products Company, Brooklyn. Composition Essentially oxyquinoline sulphate (chinosol) and water. For killing germs, leucorrhea, douching, etc. Fraudulent therapeutic claims—[N J 20365 December 1933]

Lymphin—Bika Biochemical Laboratories Philadelphia. Composition Milk sugar, starch, ground plant material, nitrogenous material, iron, calcium, sodium, potassium and magnesium phosphates, sulphates and chlorides. Alleged hormone stimulant. Fraudulent therapeutic claims—[N J 20742 February 1934]

Menthoform—Turst Mc Ness Company, Freeport Ill. Composition Volatile oils including cassia oil and menthol, formaldehyde, glycerine and alcohol. For psoriasis, sore throat, hemorrhoids, leucorrhea, etc. Fraudulent therapeutic claims—[N J 20363 December 1933]

Merchants Gargling Oil Liniment—Merchants Gargling Oil Company Lockport, N. Y. Composition Extracts of plant drugs a tarry substance tar oil turpentine oil, eucalyptol camphor ammonia and alcohol For rheumatism scurvy pleurisy sore throat, humors sore nipples toothache, ingrown toenails etc Fraudulent therapeutic claims —[N J 20376 December 1933]

Miller's Anti Mole—Miller Manufacturing Company, Lincoln Neb. Composition Nitric acid 65 per cent acetic acid 10 per cent and water For removing moles Fraudulent therapeutic claims —[N J 20372 December 1933]

Newton's Nerve—DeVore Manufacturing Company, Columbus Ohio Composition Bromides of ammonium sodium potassium and strontium extracts of plant drugs benzoate of soda and water For epilepsy sleeplessness delirium tremens etc Fraudulent therapeutic claims —[N J 20377 February 1934]

Oi De Vita—Bika Biochemical Laboratories Philadelphia Composition Essential oils including peppermint For killing germs Was not germicidal Fraudulent therapeutic claims —[N J 20744 February 1934]

O Quaka—Sigler Drug Company Springfield Mo. Composition Epsom salt extracts of plant drugs including laxative drugs and water sweetened with saccharine and preserved with a benzoate Cure all Fraudulent therapeutic claims —[N J 20393 December 1933]

Or Aid—Warners Renowned Remedies Company Minneapolis Composition Zinc chloride zinc sulphate boric acid and water Was not antiseptic For destroying germs pyorrhea etc Fraudulent therapeutic claims —[N J 20352 December 1933]

Orange Honey Compound Cough Syrup—McKesson Langley Michaels Company San Francisco Composition Tartar emetic alum honey alcohol and water Fraudulent therapeutic claims —[N J 20384 December 1933]

Orth's Prescription for the Stomach—Orth Laboratory Company East Liverpool Ohio Composition Baking soda magnesium carbonate and ginger Fraudulent therapeutic claims —[N J 20399 December 1933]

Osteon—Bika Biochemical Laboratories Philadelphia Composition Milk sugar, starch organic nitrogenous material inorganic material talc calcium phosphate potassium sodium magnesium iron and manganese sulphates and chlorides Sold as glandular stimulant Fraudulent therapeutic claims —[N J 20743 February 1934]

Painallay—Painallay Company Kansas City Mo. Composition Cresol 1 per cent small proportions of glycerine and saccharine and water 98 per cent For pain pyorrhea trench mouth etc False claims for composition and fraudulent therapeutic claims —[N J 20556 December 1933]

Petro Colon Antiseptic—Estes Surgical Supply Company Atlanta Ga. Composition Mineral oil and alcohol Possesses no therapeutic properties Fraudulent therapeutic claims —[N J 20397 December 1933]

Photo Synthetic Tea—Photo Synthetic Tea Company Lancaster Pa. Composition Ground up horsetail (*Equisetum orense*) For diabetes Fraudulent therapeutic claims —[N J 20360 December 1933]

Pyro Sana—Alhosen Chemical Company St. Louis Composition Water, 97 per cent with glycerine guaiacol and sugar For pyorrhea trench mouth etc Fraudulent therapeutic claims —[N J 20383 December 1933]

Radium Ointment—Denver Radium Service Denver Composition Potassium carbonate small proportion of isopropyl alcohol quinine camphor eucalyptol menthol soap paraffin compounds water and a radioactive substance False claims for composition since radium content was negligible —[N J 20351 December 1933]

Rheumatus—Philadelphia Capsule Company and Joseph McManus Philadelphia Composition Claimed to contain 5 grains of strontium salicylate actually contained less than 4 grains For rheumatism and gout False claims for composition and fraudulent therapeutic claims —[N J 20748 February 1934]

Rice's Remedy—Rice Colic Remedy Company Springfield Mass. Composition Alcohol about 84 per cent peppermint oil ether extracts of plant drugs For stomach and bowel trouble etc Fraudulent therapeutic claims —[N J 20587 December 1933]

Salacephan—Llewellyn Laboratories Inc Philadelphia Composition Said to contain 2 grains acetylphenetidin to the tablet actually contained not more than 17 grains False claims for composition —[N J 20594 December 1933]

Sanalt—Winsol Inc Boston Composition Epsom salt extracts of plant drugs including nuxvomica and licorice alcohol sugar and water Blood purifier etc Fraudulent therapeutic claims —[N J 20591 December 1933]

Silver Pine Healing Oil—Vicksburg Chemical Company Vicksburg Miss Composition Tar oil and turpentine oil Fraudulent therapeutic claims —[N J 20751 February 1934]

Sister Mary's Compound—Stanley Griffin Company (William R Griffin) Lowell Mass. Composition Small parts of extracts of plant drugs sulphur cream of tartar charcoal and menthol glycerine sugar and water Cure all Fraudulent therapeutic claims —[N J 20750 February 1934]

Stekettes Plin Worm Destroyer—Hazeltine & Perkins Drug Company Grand Rapids Mich. Composition Potassium nitrate 24 per cent sulphur 20 per cent phenolphthalein 17 per cent seed hulls 29 per cent chenopodium and calcium carbonate Fraudulent therapeutic claim —[N J 20561 December 1933]

Thynn Tabs—Obesity Research Bureau Inc Newark N. J. Composition A laxative drug such as rhubarb other powdered vegetable material including marine algae sugar, inorganic material with a trace of iodine Obesity cure Claim that it contained no drugs declared false Therapeutic claims fraudulent —[N J 20361 December 1933]

Trileasco Rx—Trileasco Laboratories Chicago Composition Potassium iodide ammonium acetate small proportions of a magnesium compound and a cathartic resin a trace of salicylate, sugar and water Cure all Fraudulent therapeutic claims —[N J 20396 December 1933]

Vapex—E. Fougere & Company Inc New York Composition Volatile oils including lavender and menthol and 67 per cent alcohol Misbranded because the alcohol content was not declared —[N J 20371 December 1933]

Vin Iodine Comp—Llewellyn Laboratories Inc Philadelphia Composition Claimed to contain $\frac{1}{16}$ of a grain of iodine $\frac{1}{16}$ of a grain of bromine and $\frac{1}{100}$ of a grain of phosphorus found to contain $\frac{1}{4}$ of a grain of iodine no free bromine and no free phosphorus For rickets etc Fraudulent therapeutic claims —[N J 20394 December 1933]

Vital Salve—Bika Biochemical Laboratories Philadelphia Composition Petrolatum paraffin peppermint oil and methyl salicylate For skin eruptions rheumatism etc Fraudulent therapeutic claims —[N J 20744 February 1934]

Zenar Remedies—Bika Biochemical Laboratories Philadelphia There were various products under this name described by number for whooping cough diabetes women's diseases goiter heart disease hardening of the arteries rheumatism impotency pulmonary troubles nerve and bladder remedies All declared sold under false and fraudulent claims —[N J 20729 February 1934]

Zo Ro Lo—Zo Ro Lo Inc Ada Ohio Composition Essentially epsom salt magnesium citrate citric acid glycerine menthol and benzoic acid and water Cure all Fraudulent therapeutic claims —[N J 20598 December 1933]

Correspondence

APPENDICITIS

To the Editor—In a communication in THE JOURNAL, March 17, page 862, Frederick L. Hoffman states that the question is being raised "as to whether many of the operations for appendicitis are justified and necessary." That can be easily answered by clinicians. Obviously an unnecessary appendectomy as evidenced by the absence of gross infection would hardly be a factor in increasing the death rate as corroborated by the accompanying table of cases of acute appendicitis, which shows 1,084 clean cases or closed incisions with one death.

Cases of Acute Appendicitis at Harbin Hospital

	Clean	Deaths	Drainage	Deaths	Abcess	Deaths	Total Cases	Deaths	Rate
1909 1912	35 (68%)	0	10	2	6	0	51	2	3.9%
1913 1916	64 (67%)	0	16	2	15	1	98	3	3.1%
1917 1920	134 (68%)	0	22	2	40	3	196	6	3.0%
1921 1924	102 (66%)	1	72	12	55	4	317	17	5.3%
1925 1928	325 (67%)	0	105	10	37	1	467	11	2.4%
1929 1932	334 (75%)	0	73	7	19	3	446	10	2.2%
Total	1 084 (68%)	1	319	36	170	12	1 572	49	3.1%

This table shows but little change in the death rate from year to year and the same observation may be made in many well ordered clinics where intelligent classifications are made. In the main surgical practice still adheres to convictions formed over a decade ago after much controversy on this particular point that is, to operate when a reasonable diagnosis has been made. The impossibility of an early diagnosis in certain cases, such as extremes of ages obesity and complications, constitutes an unavoidable hazard and another hazard at times exists in the absence of definite symptoms in the presence of grave pathologic developments. The hazard of extraneous conditions should be reckoned. An encouraging sign of the times may be observed in the absence in the newspapers of so many comic references to appendicitis as a fad.

It is timely for such discussions of nonsurgical writers to appear for no reliable authority claims to be able to prevent appendicitis. The menace is here to stay and safety lies only

in early diagnosis and prompt surgical treatment notwithstanding the possibility of unnecessary operation, yet operative observations cannot predicate the ultimate pathologic history of an early acutely inflamed appendix.

R. M. HARBIN, M.D., Rome, Ga.

To the Editor—Under this title in *THE JOURNAL*, March 17, Dr Frederick L. Hoffman refers to a statement in the *New Health Magazine*, London, quoting me as stating that "Appendicitis is now causing more deaths than cancer, with one person in the United States dying every twenty-nine minutes from appendicitis." As the *New Health Magazine* misquoted the statement which I made during the meeting of the American College of Surgeons last October, I wish to correct this statement. In my presentation on appendicitis, I quoted Willis (Willis, A. M. Is Progress Being Made in the Surgical Treatment of Acute Abdominal Conditions, *Virginia M. Monthly* 49:573 [Jan.] 1923) as having stated that prior to the age of 50 the mortality rate from appendicitis was four times as great as from cancer. The figure that there is one person in the United States dying every twenty-nine minutes from appendicitis was obtained by dividing the number of minutes in the year by the number of deaths during the year.

It is because of the quotation in the *New Health Magazine* being so incorrect that I wish to correct it. I have written to Dr Hoffman, informing him of the misquotation.

ALTON OCHSNER, M.D., New Orleans

TREATMENT OF DECUBITUS ULCERS WITH TANNIC ACID

To the Editor—The article by Dr Latimer on the treatment of decubitus ulcers with tannic acid (*THE JOURNAL*, March 10, p. 751) impels me to add a few pertinent suggestions as to the extension and wider scope of this treatment, which has been very successful and efficacious in my hands.

It seems incredible that, when tannic acid was first used in the treatment, and the basis for its use first outlined, it was not extended to the treatment of areas in which there were large superficial denudations of tissue. It occurred to me a few years ago that if tannic acid could tan the dead tissue of burned areas it should be of equal value in the treatment of large superficial abrasions, such as those following motor accidents, as well as in the treatment of bedsores. I have since used this method in a large number of cases and have been highly gratified at the results obtained. It has greatly facilitated the nursing care, greatly relieved pain and to a large extent decreased infections if certain procedures are used.

In the method outlined by Dr Latimer, one of the difficulties first encountered was to maintain a proper temperature. This is highly important and, if not followed, accidental burns are obtained which sometimes are more serious than the original wound. An attempt was at first made to control this by strapping an ordinary thermometer to the affected part, but this was found to be clumsy and not quite satisfactory. Also it was difficult to control the temperature if a heat lamp was used, and many accidental burns frequently result owing to the movement of the patient, so that constant shifting of the distance of the lamp is necessary. Also since no dressings and practically no clothing can be used, many are disinclined to the necessary exposure of the patient. This type of treatment also prevents the patient from moving about, forcing him to lie in a more or less constant position. As decubitus ulcers are common in debilitated patients, this enforced restraint of motion may lead to the onset of more serious trouble.

For this reason, instead of using the heat lamp a tent is made about the bed. This is easy to erect by means of two vertical bars and one longitudinal bar covered over with

blankets and bed sheets, leaving open an area at the head of the bed for air. Here the patient can lie comfortably in a constant temperature, which is easy to adjust. It has been found much better not to have any clothing or at least a minimum of clothing on the patients. They do not object to this, as the bed is enclosed on all sides and shielded from public view. The temperature is controlled by means of six 60 watt bulbs connected in parallel and not in series along the longitudinal bar. This type of connection is important, as it allows very fine adjustments of the temperature by turning on or off one of the electric bulbs. At the same time it makes the patient more comfortable by not focusing all the heat on only one area of the body but provides for an even distribution. It is good policy not to place any of the bulbs too close to the head of the bed. The patient's comfort may also be helped by placing a sheet under the lights and thus taking away the glare and the direct radiation of the heat on localized areas. A thermometer should be hung in the bed and the temperature kept within 105 to 110 F. This is very easy to do. In this tent the patient can move about quite comfortably and shift to varying positions depending on the location of the wounds. It is also of benefit to have a small flap at the head of the bed situated on the side, which the patient can lift and thus look outside without exposing himself. This is also helpful in nursing care and in feeding.

A great many errors are made in the use of tannic acid. This should be prepared fresh daily and left in the ward or at home in the form of a powder. Roughly, a tablespoonful to an ordinary atomizer makes an efficacious solution, approximately 10 per cent. This should be sprayed every fifteen to thirty minutes and no dressings used. I have found it best to spray for longer than the usual twenty-four hours and frequently do so for days. This is of value, as it helps to keep tanned the cracks and breaks that frequently form and thus lowers possible infection. Another error is frequently found at this point and that is the discontinuance of heat. The continued use of heat is essential until the wound heals entirely. The heat keeps the area dry, lowers the risk of infection and at the same time promotes healing, and obviates any need of dressings or clothing over a partially healed area, which in themselves are conducive to infection.

Senior Assistant Physician,
Willard State Hospital

MENSTRUATION AND OVULATION

To the Editor—The article in *THE JOURNAL*, February 10, by Emil Novak, together with your editorial in the same issue, concern the possibility of estimating the time of ovulation in the twenty-eight day menstrual cycle, thereby making use of the theoretical nonfertilizable periods previous to and following the discharge and death of the ovum.

Your reference to the work of Wilfred Shaw leaves an impression, which I believe erroneous, that the time of ovulation in the regular cycle is made definite by the finding of follicles in which the stage of development enables the placing of the time of rupture at the fourteenth day. The value of Shaw's observations is decreased by the small number of ovaries examined (thirty-six cases) and by the difficulty of being certain of the time of discharge of the ovum by estimating the stage of development of the corpus luteum. The degree of proliferation possible in the corpus luteum of menstruation is variable within wide limits, and apparently alterable by circulatory and inflammatory factors to which the female genital organs are peculiarly subject.

Any pathologist of considerable experience in the routine examination of ovaries removed surgically has encountered, as I

have, two and sometimes more recently ruptured follicles in one pair of ovaries. There is always the possibility that more than one ovum may be discharged within one menstrual cycle, not concomitantly as must arise in some twin pregnancies but separated by an interval of several days or longer.

I believe the anatomic evidence is insufficient for reliance to be placed on the existence of a safe period of any definiteness, even in the regular twenty-eight day cycle. I have in mind two recent cases of fertilization occurring in the week before the expected period in women with regular cycles. Such cases make very dubious the value of an otherwise interesting attempt at correlating the menstrual and ovulatory cycles.

LAWRENCE SOPHIAN, M.D., New York

[The communication of Dr. Sophian was submitted to Dr. Novak, who replies.]

To the Editor.—My paper was an evaluation of a method of contraception which is now widely practiced, more especially by those who, for such reasons as religion, are not willing to resort to the more commonly employed mechanical and chemical methods of birth control. For example, it is the only one, aside from absolute continence, which can be employed by the conscientious Catholic. My appraisal of it was based on the available evidence, clinical and physiologic. Contrary to Dr. Sophian, I feel that anatomic evidence indicates the general reliability of the plan of periodic abstinence, especially in women with regular cycles. To take extreme examples I have never, in the study of many thousands of ovaries, seen the earliest stage of corpus luteum formation (indicative of recent ovulation) in the immediately premenstrual or immediately postmenstrual phase. When dealing with later stages of corpus luteum development, no one would care to venture an estimate of the exact time at which ovulation had occurred, but there need be no hesitancy in assuming recent ovulation when one finds young corpora, such as I described in a paper in *THE JOURNAL* as far back as 1916 (October 28 of that year, p. 1285). It is on the study of such young corpora that the knowledge as to the time of ovulation was originally based, though there has been ample confirmation by other methods since then (study of early embryos, recovery of human ova by washing out the genital canal, studies on monkeys with menstrual cycles identical with the human, and so on).

The discharge of two ova, as indicated by two corpora of the same stage of development, occurs occasionally, though not often. That an interval of days should occur between the ovulations is contrary to what is known of reproductive physiology. Furthermore, multiple corpora lutea in one cycle are always, in my experience, quite identical in their histologic characteristics. Dr. Sophian's assumption of a superovulation of this sort, therefore, is a rather gratuitous one, and, so far as I know, quite original with him.

The ultimate proof of the degree of fallibility of the Ogino-Knaus method of biologic contraception will come after accurate reports are available of large numbers of cases in which it has been employed. The clinical reports thus far published come chiefly from such champions of the method as Ogino and Knaus themselves, but they are apparently accurate and they indicate the value of the plan. In Baltimore a considerable number of couples have been practicing the method with success, but always with the explanation that its degree of fallibility—for I feel quite sure it is not infallible—has not yet been determined, and that so to speak, I will not be responsible for any pregnancies which may be incurred.

Finally, a word as to Wilfred Shaw to whom I am glad Dr. Sophian makes reference, because my reply to the latter gives me the opportunity of at least a brief reference to the ungracious comments by Shaw in his paper in the *British Medical Journal* of Jan. 6, 1934 on American gynecologists in

general, and, in particular, on the views of Corner, Hartman and myself as to the possibility of anovulatory menstruation. Incidentally, I quite agree with Dr. Sophian as to the inadequacy of Dr. Shaw's study, on a small material, of the time of ovulation.

THE JOURNAL, in its editorial on the subject, quoted a harsh paragraph from Shaw concerning my views on anovulatory menstruation, so clearly established in both the human being and the monkey, as I showed in my paper. Further confirmation has just come from studies in Schroder's clinic, as reported by Tietze at the recent meeting of the German Gynecologic Society. I have already replied to Shaw's paper in a communication published in the *British Medical Journal* of March 3, having been moved to do this by the sneering attitude exhibited by Shaw toward American gynecologists and by the oracular role which he assumes in the disposition of these still much discussed problems.

His chief complaint seems to be that we persist in including, under the term "menstruation," cases in which ovulation and corpus luteum formation do not occur, even though the menstrual bleeding is just as rhythmic as in the other more common type, so that there is no possibility of making a clinical distinction. In other words, we cling to the time-honored definition of menstruation as a rhythmic physiologic discharge of blood from the uterus, while he prefers to limit the term to those cases in which the periodic bleeding is associated with ovulation and corpus luteum formation. There is, of course, no objection to an expression of honest difference of opinion of this sort. I believe that American gynecologists will resent the tone of Shaw's paper, in which any new idea emanating from America is scoffed at, and apparently for that reason. The interrelations of British and American gynecologists have always been much too pleasant to permit the thought that Shaw's views are shared by any number of his colleagues.

EMIL NOVAK, M.D., Baltimore

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

USE OF ROENTGEN RAY IN ERYSIPELAS

To the Editor.—Kindly give me your opinion of the treatment of erysipelas with x-rays. Please omit name. M.D. Texas

ANSWER.—The roentgen treatment of erysipelas is a well established method. Among others, Magelhaes and Schmidt both reported excellent results in 1917. Hesse reported further successes in 1918, Schrader in 1921, and more recently Harbinson and Lawson in 1927 (*California & West Med* 26:485 [April] 1927), Platou Schlutz and Collins (Erysipelas. A Clinical Study of the Treatment of This Disease, *Am J Dis Child* 34:1030 [Dec.] 1927) and Notger von Oettingen (*Munchen med Wchenschr* 79:1640 [Oct. 7] 1932). All these reports agree in stating that within twelve to twenty-four hours a large percentage of the cases become afebrile, in a smaller group the fever gradually diminishes and is lost after several days, and in all these the pain, swelling and discomfort disappear in a few days. In some of them there is a recurrence of the fever but most of these cases yield to a second irradiation. The percentage of failures is small.

Although erysipelas is a disease notably eccentric in its course which makes the evaluation of therapeutic measures difficult the good results of roentgen therapy are too prompt and occur in too large a percentage of the cases to be explainable as coincidence or spontaneous improvement.

The report of Platou Schlutz and Collins is of particular interest because they give a comparison of the results of roentgen treatment with the older methods and with the antitoxin treatment. Temperature was reduced most promptly by roent-

gen rays, returning to normal in an average of 15 days, as against 22 days for the antitoxin treatment and from three to four days for the older methods. Symptoms subsided on an average in two days after roentgen treatment, 38 days after antitoxin and on an average in eight days after the older methods of treatment. The mortality in infants was 80 per cent under old methods and 50 per cent under roentgen treatment. The general mortality in their series was 23 per cent for cases treated by other measures and 6 per cent each for roentgen rays and antitoxin. The diseased area extended after the beginning of treatment in 24 per cent of the cases treated by roentgen rays, in 40 per cent of those treated by antitoxin, and in 68 per cent of those given other treatment. In ten particularly severe cases they combined roentgen treatment with the use of antitoxin with good results and they believe that this is the best method of treatment for erysipelas.

In the older series the dosage of roentgen rays was high, a full erythema dose in all and more in some series, but in the latest report cited, that of von Ottingen, excellent results are reported for moderate doses, not over a fourth of the erythema dose repeated not more than once. This author points out that there is no value in waiting a week before giving the second dose, as some stipulate, but that the second exposure should be given on the second day after the first one if results have not been satisfactory. Most authors state that they used about 100 kilovolts unfiltered, and Harbison and Lawson point out the necessity of including a 3 cm margin of apparently uninvolved skin in order to include all infected areas.

Favorable reports have been made of the value of ultraviolet irradiation in early erysipelas, although Finsen failed to obtain good results in his early experiments. It must be conceded that the use of roentgen rays, antitoxin and ultraviolet radiation has made possible a much more cheerful prognosis for the sufferer from erysipelas than was possible before.

FASCIA LATA IN FRACTURE OF PATELLA

To the Editor—Would you kindly give me information concerning the use of fascia lata in the repair of fracture of the patella? M D

ANSWER—Some of the best articles on the use of fascia lata in the repair of fracture of the patella are those by Gallie and LeMesurier in the *British Journal of Surgery*, October, 1924, and in the *Journal of Bone and Joint Surgery*, January, 1927. They believe that transplants, when given an adequate supply of lymph, continue to live practically unchanged. They heal to whatever structure they are placed in contact with by ordinary scar, the strength of which depends on the degree to which the surfaces that come in contact with it are denuded of areolar tissue and the scarification area of these surfaces.

The technic is as follows. The fascia lata is obtained from the outer surface of the thigh by long incision or by using the fascia lata strippers designed by Masson—a modification of the Mayo vein stripper.

Holes are drilled into the patella and the fascia lata, threaded on a special needle, is inserted into these holes. A splint is applied.

In their operation the bone fragments are drawn as closely together as possible and are held in this position by a heavy loop of fascia lata passed through drill holes. The ends of the loop are freed from areolar tissue and woven through each other and sutured with catgut.

By this means the continuity of the quadriceps is established and a considerable portion of the normal extensor power restored.

If the ununited fracture is close to the upper or lower border of the patella the drill holes are made in the large fragment only, and the loop of fascia is drawn through the quadriceps tendon or the ligamentum patellae, through a transverse tunnel made with a narrow knife. The presence of a small flake of bone on the end of the tendon prevents the loop from coming out.

The operation consists in bringing the freshened surfaces of the fragments together and inserting a loop of fascia lata 1 inch in width through two vertical holes in the upper fragment and transversely through the ligamentum patellae just below the lower fragment. The transverse rent in the lateral expansion of the quadriceps tendon and the capsule of the knee joint is closed with a living suture of fascia threaded on the needle. Gallie and LeMesurier transfix each stitch combining it with a single hitch. They end the suture by passing it through itself, splitting and tying the ends in a triple knot and transfixing the whole by a catgut or silk suture.

It is interesting to note that Hoguet has used fresh fascia lata from one patient to another with complete satisfaction.

Alcohol-preserved fascia may be used for the repair when, for any valid reason, autogenous grafts cannot be used.

Masson's method of obtaining fascia lata for living suture is indicated when only a small amount is necessary. In any case in which it is necessary to use three or four living sutures more than 20 cm in length, it is advisable to make a long incision on the side of the thigh.

After the removal of the necessary amount of fascia lata the opening in the fascial sheath should be closed in order to prevent a muscle hernia. In closing such a wound, a strip of fascia can be carried from one side to the other and back to the original side at a point situated at about the middle of the wound, or it can be closed by interrupted or continuous catgut sutures, reducing in great measure any bulging of the vastus lateralis muscle.

Masson's original article appeared in the *Proceedings of the Staff Meetings of the Mayo Clinic* (489 [March 20] 1929).

Fascia lata is obtainable commercially in tubes containing strips 8 inches long and from one-fourth inch to one half inch wide.

VITAMIN A FREE DIET FOR RABBITS

To the Editor—I am desirous of obtaining a vitamin A free diet for rabbits. I have tried unsuccessfully to obtain this information and finally remembered that you might be so kind as to help me out. Kindly omit name. M D Pennsylvania.

ANSWER—An extensive study of the effect of diets devoid of vitamin A on rabbits has been conducted by V E Nelson and his co-workers at the Iowa State College Experiment Station in Ames. (The results are reported by Nelson, V E, and Lamb, A R. *Am J Physiol* 51:530 [April] 1920 and Nelson, V E, Lamb, A R, and Heller, V G, *ibid* 59:335 [Feb] 1922.) Rabbits were compared with rats as to their requirements of vitamin A by the use of a ration consisting of commercial casein 20, dextrin 70, salts 5, wheat embryo 5 and alfalfa meal 25 parts. The alfalfa meal was extracted with hot alcohol for ninety-six hours to remove vitamin A, but the casein was not purified. This diet proved capable of supporting slow growth in rats for two or three months, but rabbits varying in age from 3 to 8 weeks developed xerophthalmia in from two to eight weeks, depending on the age of the animal at the beginning of the experiment, and died in from two to three months.

Another ration consisting of oats 60, gelatin 10, agar 5, salts 5, dextrin 20, and extracted alfalfa 20 parts, produced a chronic form of xerophthalmia in rabbits.

To compare the vitamin A requirement of growing pigs, rabbits and rats, the following ration was used: white corn 55, linseed meal 22, ground oats 15, tankage 5, and salt mixture 3 parts. A sow was fed this ration during the gestation and suckling period. Four pigs were farrowed, three of which lived but remained unthrifty and grew slowly. No signs of eye trouble were observed at any time, but when the ration of one of the pigs was supplemented with an allowance of about 10 Gm of butter fat, rapid improvement in condition resulted. The same ration when fed rabbits caused xerophthalmia and death in one case after six weeks and in another case slight xerophthalmia, which was cured by the addition of 5 per cent of butter fat to the ration. Four rats on the same ration grew fairly well to maturity but the young that were born were not suckled and died in a few hours. The authors conclude that the pig may be classed with the rat in requiring less vitamin A than the rabbit.

FACIAL PARALYSIS AFTER MASTOIDECTOMY

To the Editor—I should like to secure possible information from you on the incidence (statistical) of facial paralysis following radical mastoidectomy together with the medicolegal aspects and any cases of such a nature that have been tried. I would greatly appreciate a review of the literature on this subject from a medical standpoint. M D Wis

ANSWER—It has been impossible to obtain definite data regarding the incidence of frequency of facial nerve paralysis following radical mastoidectomy. Many cases are not reported in the literature, partly, no doubt, because a patient in whom paralysis has occurred seeks the advice of various physicians, so that the original operator may not have the opportunity to follow up the cases in which the postoperative paralysis has developed. A number of cases have at various times been abstracted in the medicolegal department of *THE JOURNAL*, as for instance the case of *Schoening v Smith* (N D) 231 N W 278 (*THE JOURNAL*, April 25, 1931, p 1432), in which the Supreme Court of North Dakota upheld the trial court in finding that the plaintiff had failed to substantiate his claim,

basing his decision on the well settled rule that a patient must connect his injury with negligence on the part of the physician.

In another case, *Brant v Sweet Clinic*, 8 P (2d) 972, decided by the Supreme Court of Washington, 1932, and abstracted in *THE JOURNAL*, Oct 15, 1932, page 1380, the defendant clinic was held liable for damages to the patient for facial paralysis following the removal of a branchial cyst.

Generally speaking, one may say that a suit arising as a result of injury to the facial nerve following a mastoidectomy does not differ in principle from a suit arising out of any other operation. In every instance it may be claimed that the physician was negligent, that he lacked due knowledge and the proper amount of skill or failed to exercise that skill, that he did not use his best judgment and that the patient was actually injured because of a fault on the part of the physician. Unless the plaintiff can prove that the physician failed in any of these requirements, he is not entitled to recover damages as a result of the operation. ERGOSTEROL AND STONE FORMATION

To the Editor—Is there any experimental or reliable clinical evidence that the administration of ordinary doses or large doses of irradiated ergosterol causes or is followed by the formation of stone in the uro genital tract?

THOMAS W. MALONEY, M.D., Geneva N Y

ANSWER—In a paper by W E Dixon and J C Hoyle on the effects of irradiated ergosterol in large doses (*Brit M J* 2:832 [Nov 10] 1928) there is a report of the production of calculi in animals after administration of large doses of viosterol (irradiated ergosterol). The authors stated that in their experiments lack of vitamin A was certainly not the explanation of the formation of calculi. All the animals were given a correct diet, with an adequate allowance of vitamins A, B, C and D. The control animals were in every way normal, and infection of the urinary tract was present in no case, control or experimental. In these experiments the origin of the stones must be entirely different from that of those previously described, in that it must be due to excess of viosterol. The authors regard it as probable that the viosterol facilitates the absorption of calcium and phosphate from the intestine. They add: "All this evidence suggests that calculi formation may accrue by the excretion from the kidney of larger amounts of calcium and phosphate than can be held in solution by the urine and this we believe is the explanation of the present observations."

They also add that the amounts of viosterol necessary to cause urinary calculi were so large that the condition has obviously little clinical importance. The German observers, however, obtained much more marked changes with smaller doses and if their experiments are valid an excess of vitamin D may not be without clinical interest.

The occurrence of calculi is also described by J C Hoyle (*Toxic Effects of Irradiated Ergosterol J Pharmacol & Exper Therap* 38:271 [March] 1930).

There is evidence of marked histologic changes in the kidneys after the use of large doses of viosterol. Spies and Glover (*Renal Lesions with Retention of Nitrogenous Products Produced by Massive Doses of Irradiated Ergosterol Am J Path* 6:485 [July] 1930) conducted experiments on rabbits with a product having 1,000 times the antirachitic potency of ordinary cod liver oil. This produced severe toxic manifestations. Extensive pathologic changes occurred in the renal tubules. Calcium was deposited in and near the basement membrane of many of the severely damaged tubules and to some extent

within the degenerated epithelium. The collecting tubules showed large hyaline casts containing calcium. There was calcification of the glomerular capsules. Whether calcareous debris or stone was actually found in the bladder is not recorded. Somewhat similar results are described for rats by Shohl, Goldblatt and Brown (*J Clin Investigation* 8:505 [June] 1930). The calcium deposits appear to be a manifestation of metastatic calcification. Nothing comparable to this has been described for "ordinary doses" of viosterol.

RESISTANT URTICARIA

To the Editor—I am writing to ask whether there is anything else you can suggest for a case of erythema multiforme of the urticarial type which has run since July 1932. The patient has been skin tested for everything I can think of he has had cultures of the nose throat blood and stool with intradermal tests of the organisms recovered. He has been on elimination diets. I gave the vaccines made from his cultures over a period of time without benefit. Absolutely the only contributing factor known was that he had some exceedingly severe attacks following hikes in the mountains as has been his custom. In these attacks after the lesions had become confluent the ankles and feet and wrists and hands swelled massively. Any exercise seems to bring on the lesions in direct proportion to the amount of the exercise. However the attacks come in waves at intervals of from one to three weeks with periods of comparative freedom between. He has had salicylates, calcium viosterol solution of anterior pituitary and histamine injections among other things. I have tried epinephrine and atropine without relief. The only relief seems to be in soaking the hands and feet in very hot water. Alcohol helps a little. The patient is 34 years of age married and making a fair living. He has an allergic history in that he had had hives hay fever and a little asthma before. I have wondered whether it might not be significant that he was taking bay fever pollen for the fourth year when this disease began. In fact he took it during the winter of 1931-1932 and had just attained his maximum dose. He stopped at once and had a little hay fever that summer but none in 1933 (with no pollen). He suffers intensely. The lesions have appeared everywhere except on his face and when they appear on the palms and soles the itching burning pain that results is terrible. He has no conflicts that I know of. Although I recognize the essential neurotic element in the condition he has seen a very capable dermatologist who told him he would probably recover in time and offered no additional treatment. Of course I can find no foci of infection. His general condition remains very good. He weighs 175 pounds (80 Kg) for instance and is 5 feet 11 inches (180 cm) tall. I might say that I had him play golf regularly last summer with the idea of immunizing him against exercise with possibly a little benefit. I would greatly appreciate any help. Please omit name and address.

M D Washington

ANSWER—The patient has one of the obstinate types of urticarial eruptions. He has an allergic background, and the picture is further complicated by the fact that physical exertion provokes an angioneurotic type of eruption. Assuming that all foci of infection have been ruled out (roentgenograms of the teeth revealed no abscesses) and there is absolutely no ingestion of drugs, such as those in the coal tar group, or cathartics containing phenolphthalein, the following additional therapy is suggested. The use of autologous therapy by withdrawing 10 cc of the patient's own blood, and reinjecting it intramuscularly. This may be given once or twice weekly. If there is no response, then the antianaphylactic effect of peptone in 0.5 Gm doses in capsules, twenty minutes before meals, should be considered. This may be combined with mercury with chalk, 0.065 or 0.13 Gm, after meals. Further therapy consists of limiting animal foods and giving *Bacillus acidophilus* by mouth. Rest and freedom from nervous and emotional factors are essential to any scheme of treatment in this case.

GLYCOSURIA AND POTENTIAL DIABETES

To the Editor—In an otherwise normal examination a trace of sugar was found in the urine. The following day 100 Gm of dextrose was given by mouth and the two hour urine sample showed 0.4 per cent sugar. Four days afterward a sugar tolerance test was run (John Wu) with the following results: fasting 90 mg per hundred cubic centimeters one hour 148 mg two hours 118 mg. Should this case be classified as one of renal glycosuria or of potential diabetes? Kindly omit name.

M D Missouri

ANSWER—It is always safer to regard a case such as this as one of potential diabetes until proved otherwise. The data as furnished suggest a normal response to the sugar tolerance tests. The fasting blood sugar of 90 mg must be considered normal. The fact that there was 0.4 per cent sugar following the ingestion of 100 Gm of dextrose is not conclusive evidence for a differential diagnosis between renal glycosuria and alimentary glycosuria.

There are further criteria that must be established before one is justified in accepting a final diagnosis of renal glycosuria. These are first a relatively slight or no parallelism between intake and excretion of sugar. Whereas in true diabetes the patient will ordinarily excrete sugar in a quantitative relation-

ship to the amount of carbohydrate taken in, the patient with renal glycosuria will show no such quantitative comparisons, and it will be found extremely difficult to make the glycosuria disappear completely even on a strict diet. Also it is important to note the absence of the usual diabetic symptoms in a patient with renal glycosuria, and a final test is that this patient does not develop diabetes.

BRAZERS' CHILLS OR METAL FUME FEVER

To the Editor—Can you give me any information on brazer's chills? I have a patient who has had four or five seizures within the past year. He uses a Tobin bronze brazing rod which is a compound composed principally of brass and zinc. The zinc passes off in fumes which are inhaled and produce a severe chill lasting from three to six hours. If you have any literature please give me references as I am interested in learning more on the subject.

O VAN DER VELDE M D Holland Mich

ANSWER—Tobin bronze is likely to contain 60 per cent of copper, 38 per cent of zinc and 0.66 per cent of tin. "Brazers' chills" are one form of 'metal fume fever'. This occupational disorder is likely to arise around welding operations, metal founding, torch metal cutting, and galvanizing. Zinc is perhaps the commonest cause of the disturbance, possibly because of the relatively low temperature at which zinc is volatilized. "Zinc chills," "brass founders' ague" and "brazers' chills" are all descriptive of the same type of ailment, for which there are many other descriptive terms. In the typical case, symptoms commonly do not arise until after the end of work exposure. These include marked chilling somewhat similar to a malarial chill, weakness, lassitude and profound thirst followed after a few hours by sweating and still later by a distaste for food. No chronic form of the disease is known and ordinarily the worker does not lose time from his employment. At times there is mild inflammation of the eyes and respiratory tract. Apparently workers continuously exposed become less susceptible. Conversely, new workers readily may be affected. In foundries the condition is more prevalent during the winter months and during wet, snowy weather. Further discussion may be found in "Industrial Health," by Kober and Hayhurst, Philadelphia: P. Blakiston's Son & Co., 1924 and "Industrial Poisons in the United States" by Alice Hamilton, New York, Macmillan Company, 1929. Numerous articles have appeared in the *Journal of Industrial Hygiene* during the past ten years under such titles as "metal fume fever," "zinc poisoning" and "brass founders' chills."

TIMING IN IMMUNIZATION AGAINST INFECTIOUS DISEASES

To the Editor—Would you kindly give me the following information on immunizations. I should like to know just how much time should be allowed between the prophylactic treatments for smallpox, diphtheria and whooping cough (Sauer vaccine). Since it takes anywhere from two to four months to acquire these various immunities, I am not exactly sure as to whether the specific antibodies will form simultaneously or whether it is best to wait until one immunization is acquired before starting another one. Please omit name. M D, Massachusetts

ANSWER—The best plan is to allow four months to intervene after each of these three important immunization procedures. Because whooping cough causes more deaths in children under 2 than do diphtheria, measles and scarlet fever combined, it is prudent to immunize first against whooping cough—preferably during the second half year of life. Four months later a single alum toxoid injection against diphtheria should be given. Four or more months thereafter, when the Schick test is performed (preferably in the spring or autumn), the smallpox vaccination should be done.

TREATMENT OF WORMS IN DOGS

To the Editor—Kindly outline a simple and effective treatment of round and flat worms in dogs. Please omit name. M D, Pa

ANSWER—Perhaps the commonest roundworm in the dog is *Ascaris mystax* and the commonest flatworm *Dipylidium caninum*, although many other tenias may be found. The principles of treatment are the same as for man, i.e., the administration of an anthelmintic after a comparative fast as in the morning followed by a cathartic in two or three hours. Some of the commonly used anthelmintics for roundworms are santonin, thymol, carbon tetrachloride and oil of chenopodium and for flatworms oleoresin of aspidium and pelletierine tannate. These may be given in approximately the same dose as for man to adult dogs, and proportionately less for young puppies. Suitable cathartics are mild mercurous chloride, magnesium sulphate, and so on.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILIGOLOGY Written Examinations will be held in various cities April 30. Oral Cleveland June 11-12. Sec. Dr. C. Guy Lane, 416 Marlboro St. Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Oral (all candidates), Cleveland, June 12. Sec. Dr. Paul Titus, 1015 Highland Bldg. Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY Cleveland June 11 and Butte Mont. July 16. Application must be filed at least 60 days prior to date of examination. Sec. Dr. William H. Wilder, 122 S. Michigan Bldg. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Cleveland June 11. Sec. Dr. W. P. Wherry, 1500 Medical Arts Bldg. Omaha.

ARKANSAS Basic Science Little Rock May 7. Sec. Mr. Louis E. Gebauer, 701 Main St. Little Rock. Regular Little Rock May 14-15. Sec. Dr. A. S. Buchanan, Prescott. Homeopathic Little Rock May 8. Sec. Dr. Allison A. Pringle, Eureka Springs. Eclectic Little Rock May 8. Sec. Dr. L. L. Marshall, 820 W. 14th St. Little Rock.

CALIFORNIA Reciprocity San Francisco May 16. Sec. Dr. Charles B. Pinkham, 420 State Office Bldg. Sacramento.

CONNECTICUT Basic Science New Haven June 9. Prerequisite to license examination. Address: State Board of Healing Arts, 189 Yale Station, New Haven.

IOWA Iowa City June 5-7. Dir. Division of Licensure and Registration Mr. H. W. Grefe, Capitol Bldg. Des Moines.

NATIONAL BOARD OF MEDICAL EXAMINERS The examinations in Parts I and II will be held at centers in the United States where there are five or more candidates. May 7-9 (limited to a few centers). June 25-27 and Sept. 12-14. Ex. Sec. Mr. Everett S. Elwood, 225 S. 15th St. Philadelphia.

NEBRASKA Basic Science Omaha May 12. Medical Omaha June 8-9. Application must be filed at least fifteen days prior to date of examinations. Dir. Bureau of Examining Boards Mrs. Clark Perkins, State House, Lincoln.

NEVADA Carson City May 7. Sec. Dr. Edward E. Hamer, Carson City.

WYOMING Cheyenne June 4. Sec. Dr. W. H. Hassel, Capitol Bldg. Cheyenne.

ADVISORY BOARD FOR BOARDS CERTIFYING SPECIALISTS

Announcement is made of the formation of the Advisory Board for Medical Specialties, previously referred to editorially in THE JOURNAL. The purpose of this advisory board is to coordinate the activities of the various official groups already concerned with postgraduate medical education in the specialties, and to standardize their methods of work and the certification of medical specialists by the existing examining boards.

It is composed of representatives from the following groups: the Association of American Medical Colleges, the American Hospital Association, the Federation of State Medical Boards of the United States, the National Board of Medical Examiners, the American Board of Ophthalmology, the American Board of Otolaryngology, the American Board of Obstetrics and Gynecology, the American Board of Dermatology and Syphilology, and the American Board of Pediatrics. Examining boards in other specialties may be eligible for representation on this board on meeting certain high standards of qualification.

The officers are president, Louis B. Wilson, Rochester, Minn.; vice president, J. S. Rodman, Philadelphia; secretary and treasurer, Paul Titus, Pittsburgh; members of the executive committee, W. P. Wherry, Omaha, and W. B. Lancaster, Boston.

The Advisory Board for Medical Specialties should have an important influence on undergraduate medical education as well as on graduate education in the specialties. It will assist in the active investigation and listing of postgraduate training facilities both in the United States and in Canada, and to a lesser extent abroad, much of which has already been done in this country by the Council on Medical Education and Hospitals of the American Medical Association. It should be an important influence in effecting a general improvement in the standards of practice in the various specialties.

It is expected and planned that the Advisory Board for Medical Specialties will be reportable to and work under the general direction of the Council on Medical Education and Hospitals of the American Medical Association.

The next edition of the American Medical Directory plans to publish information about the acceptable special boards as well as to indicate those physicians who are diplomates of the boards. Plans are likewise being formulated for the proposed publication of a directory of diplomates which shall also contain

information regarding postgraduate training facilities, special residencies available, and general qualification necessary for certification and such official recognition as a specialist in any given branch of medicine

The next meeting of the Advisory Board will be held in Cleveland, Sunday, June 10, or immediately prior to the next annual session of the American Medical Association

Kansas December Report

Dr C H Ewing, secretary, Kansas State Board of Medical Registration and Examination, reports the written examination held in Topeka, Dec 12-13, 1933. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. Eight physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Howard University College of Medicine	(1933) 83	84	85

Book Notices

Neurology By Roy R Grinker Associate Professor of Neurology the University of Chicago Cloth Price \$8.50 Pp 979 with 401 illustrations Springfield Ill & Baltimore Md Charles C Thomas 1934

This volume presented primarily as a textbook for students of medicine, will also be found by general practitioners to be exceedingly practical as a reference work for them. It is developed according to a simple plan, which adapts it especially to such use. It begins logically with the embryology and anatomy of the central nervous system, including a discussion of the cerebrospinal fluid. There is a chapter on the reflexes and the pathology of the nervous system, followed by an outline of the technic of neurologic examination. The author then discusses the various portions of the nervous system in detail. There is a chapter on tumors of the peripheral nerves and spinal cord, and also one on muscle tone and posture, which are associated with chapters on the cranial nerves and the cerebellum. The latter half of the volume concerns the anatomy and physiology of the blood supply to the central nervous system and the diseases of the cerebrospinal vascular system. Succeeding chapters are concerned with infection, syphilis, trauma, atrophies, epilepsy, headaches, dyscrasias, toxins, degenerative diseases and developmental defects.

The book is exceedingly well written and the illustrations, while not profuse are practical. They are selected with a view to aiding comprehension of the text. The language is didactic. For example, the treatment of intracranial tumors begins, "There is but one logical treatment for neoplasms, intracranial or otherwise, which endanger the life and health of the patient and that is their complete removal." Then, however, follows a consideration of the indications for operative procedure which points out when such operations are unwarranted. There are also discussions of the use of roentgenotherapy. Each of the chapters is followed by a well selected bibliography of the periodical and book literature of the subject concerned.

Of special interest to the general reader are the chapters on epilepsy and headaches. The classification of epilepsy is based on the vast periodical literature of recent years. Each of the hypotheses is discussed thoroughly in relationship to practical considerations. In his therapy of epilepsy the author considers dietary control, the use of various types of drugs, surgical methods and dehydration, and the question of institutionalization. It is interesting to observe that he has but little to say relative to the treatment of migraine on an allergic basis.

Altogether, the book must be considered a most useful volume for the general reader, largely because of the simplicity and directness of the presentation and also because it is written so definitely with the needs of students and beginners in mind.

Erkrankungen des Herzmuskels und der Herzklappen 11 Oeynhau sener Arztevereinskurs 6 und 7 Mal 1933 Herausgegeben vom Arzte veretn zu Bad Oeynhau sen Paper 1 rlee 5 marks Pp 94 with 10 illustrations Dresden & Leipzig Theodor Steinkopff 1933

This is a collection of lectures recently given at Bad Oeynhau sen. H. Reins lecture is a brief summary of his recent excellent work on the physiologic factors governing coronary circulation. F. Büchners lecture presents the present status of the relation of the anatomic lesions to the clinical and electrocardiographic observations in coronary thrombosis and sclerosis. The author emphasizes that the pain in angina may be due to disseminated focal necrosis of the heart muscle when obvious gross infarcts are absent. A. Röhl gives an authoritative succinct summary of the modern knowledge of metabolism as related to heart disease. E. Laquer in a lecture on endocrine disorders of the heart has brought down to date the relation of the thyroid gland to cardiac disorders and has briefly presented the effects of the other endocrine glands on the circula-

tion. F. Volhard discusses the differential diagnosis of valvular defects. This lecture is a clear evaluation of the various physical signs to be found in patients with valvular disease. Emphasis is placed on the fact that the diagnosis of the valve lesion is only the beginning of the problem facing the physician. Throughout, the thought is stressed that too much attention should not be paid to the auscultatory observations at the risk of overlooking other physical signs. The other three lectures, given by C. Kroetz, C. Hegler and O. Krayer, are less instructive than the lectures just discussed. The collection of lectures has sufficient merit to warrant recommending the book to the internist interested in heart disease. The lecturers are cognizant of the important part the American school has taken in advancing knowledge in these fields. The attempt of these lecturers to incorporate the recent advances in physiology in a clinical presentation is commendable and might easily serve as a stimulus for similar attempts in this country.

The Modern Treatment of Syphilis. By Joseph Earle Moore, M.D., Assistant in Medicine, The Johns Hopkins University. Cloth. Price \$5. Pp. 73, with 41 illustrations. Springfield, Ill. & Baltimore: Charles C. Thomas, 1933.

Some one has said "There are lies, damned lies and statistics." This monograph goes far to dispute the truth of this assertion. What more natural than that the author, brought up under the shadow of Raymond Pearl, should use a statistical approach to his subject? Not that the reader will in any way find the book hard reading—the contrary is the case. The text is extremely well written, is interesting, and, owing to the data furnished, is most convincing.

It is impossible in the limits of a book review to discuss the monograph as it deserves. The volume has the marks of a master hand and is a real contribution from American medicine to world syphilology. The chapters on the prognosis of syphilis, untreated and treated, the treatment of early syphilis and the treatment of latent syphilis are exceedingly well done. The author, however, reaches his real heights in discussion of the treatment of syphilis complicated by pregnancy and the treatment of cardiovascular syphilis and in the chapters devoted to neurosyphilis. One gathers from reading these chapters that Moore feels that the Wassermann test is not used as universally as it deserves, and that many times a case of syphilis, if it had been diagnosed earlier, would have been far more amenable to treatment. Yet as the convincing data are spread before the reader, syphilis is, after all, not so hopeless a problem. Thus, uncomplicated syphilitic aortitis recognizable on the basis of symptoms and signs, has a probable average duration of life of from ten to twenty years if adequately treated (p. 281). The author shows that much can be hoped for in ocular syphilis if proper treatment is instituted. The discussion of the treatment of syphilis of the central nervous system shows the touch of a real student of the subject. After all, much of the ravages of this disease in nerve tissue can be either avoided or warded off if diagnosed early and treated properly with the medicaments now at hand.

It may be noted that throughout the volume the author recommends only such antisyphilitic drugs as are recommended by the Council on Pharmacy and Chemistry of the American Medical Association.

Moore feels that sodium thiosulphate is of no value in combating arsenical reactions, at least, one can hardly agree with his views that it is useless when injected locally in arsenical extravasations. And one must certainly object to the author's stand that excretion studies of heavy metals are "only of value to determine possible dangers of toxic effects." Outside of bismarsen, Moore uses and recommends bismuth salicylate suspension in oil as his sole bismuth salt for the treatment of syphilis. Excretion studies show that the salicylate is but slowly absorbed and has a low excretion curve running for many weeks or even months after a few injections. There are many occasions when other more suitable bismuth salts should be used. Mention is made on page 123 of sclerosing myositis from mercury salts, with the statement that, since bismuth was being employed, these were no longer seen. Would not 'paraffinoma' be a better term for these cases? The reason they are no longer seen is not that bismuth instead of mercury is used but rather that vegetable oils are used instead of

mineral oils as suspending agents. The dosages suggested for the arsphenamines are perhaps higher than some syphilologists use, and certainly higher than those recommended by the Council on Pharmacy and Chemistry. The author evidently feels that higher dosages are justified in some instances. On page 144 it is stated that a Wassermann test may be taken even after an arsphenamine injection. It is doubtful whether this is good practice. Moreover, it is surprising that the effects of nonspecific therapy in interstitial keratitis are not more clearly evaluated—especially malaria. As to the suggested use of x-rays for this affliction, as recommended by some German investigators, though not used personally by Moore, the objection arises of probable cataract formation at a later date. In discussing congenital syphilis the author might well have placed more emphasis on the use of neoarsphenamine administered subcutaneously in the scalp. Reference is made of third generation syphilis by way of a congenitally syphilitic mother. While the possibility of syphilis in the third generation through this route is conceivable, there are many other contingencies that enter into the problem.

But these are only minor criticisms of a monograph that deserves to be in the hands of every physician. The book is a classic for which a prediction of many editions is made. The binder and the printer have done their work well. The numerous charts and illustrations are well arranged.

Ärztliche Fragen. Vorlesungen über allgemeine Therapie. Von Viktor von Weizsäcker. Paper. Price 1.80 marks. Pp. 90. Leipzig: Georg Thieme, 1934.

This brochure represents a course of lectures on general therapeutics in which the author attempts to orient his audience as to the nature of treatment. "There is one therapy only; the remedies merely are multiple." The subject is presented with rather involved, often definitely obscure, diction and a strong leaning toward abstract philosophy. The propositions, for instance, that health has something to do with truth, and sickness with untruth, he attempts to establish by sophistries. A considerable amount of thought is devoted to the adjustment of medical practice to "Kassenpraxis," now almost universal in Germany. Indeed the most interesting portions of these lectures are those dealing with the relation of medicine to the state, and these breathe the spirit of the new Germany in such phrases as: "It is the state which asks the question as to the individual's maintenance-worthiness (erhaltungswürdigkeit) and which executes its own decisions. Neurotic inability to work is a much more serious charge against the social order than gross organic disease. In the newly developing world, the policy of destruction of undesirables, of prevention of their propagation, and of maintaining a high degree of working capacity will be largely in the hands of the medical profession so that medicine and politics will have to go hand in hand. Psychotherapy and social therapy will have to be added to medical practice, and special pathology and therapy must be kept from disintegrating effective treatment by analysis into incompatible factors. From time to time the physician will have to sacrifice care and help for the individual to the demands of the body politic."

A Handbook of Psychiatry. By John H. Ewen, M.R.C.P., D.P.M., Assistant Medical Officer, Surrey County Mental Hospital, Netherne. Cloth. Price \$4.75. Pp. 267. Baltimore: William Wood & Company, 1934.

This volume is intended to do for psychiatry what the synopsis of Tidy has done for medicine. It is a brief outline in the 1, 2, 3 fashion, of the various mental disorders, each treated as an entity, which are outlined in the usual textbook method of etiology, pathology, symptomatology and treatment. There will always be some question as to the value of outlines. Many teachers feel that they should be withheld from the student, but certainly they have their place as brief "refreshers." For this reason the present volume can be commended, in spite of a few typographical errors and the necessary brevity, which leaves new and unusual topics unexplained. The psychoneuroses are insufficiently discussed, malingering is given only two pages, and for the American reader, some of the terminology and the medicolegal aspects will be found to be solecistic. The glossary is too short and, although authors are cited, the book is not annotated.

Röntgentherapie in Tabellenform Von Dr. Immanuel Markovits Vorstand des Röntgenlaboratoriums im Krankenhaus des Stadt Armenhelfes in Budapest. Paper. Price 10 90 marks 1 p 1+3 with 40 illustrations Leipzig Georg Thieme 1934

In line with the author's previous publications, introducing the tabular analysis of the pathologic, clinical and roentgen observations in various bone and joint diseases and in internal medicine, there now appears this acceptable volume on roentgen therapy in tabular form. The author calls attention to the ever changing standards in radiation therapy and the necessity of keeping up with the developments in physical, biologic and clinical advances. There is a brief history of the development of roentgen dosage and measurements. Many of the radiation effects are adequately explained, but the author admits that a number of the indications are empirical and that the method by which the rays produce their good effect is not clear. He particularly refers to the effect of radiation therapy in the relief of pain, which is entirely unexplained but a fact. The various indications include the blood dyscrasias, angina pectoris, asthma, thyroid disease, diabetes, Mikulicz disease, pyloric stenosis, hyperacidity, duodenal and gastric ulcer, and a number of other internal disorders, acromegaly, brain tumors of various kinds, multiple sclerosis, syringomyelia and other neurologic diseases, a long list of surgical and orthopedic lesions, in many of which the x-rays have not in the experience of some workers proved to be of great help, a number of gynecologic indications with none of which exception could be taken and a series of urologic, pediatric, rhinolaryngo-ophthalmologic, odontologic and dermatologic indications. Each disease is considered under the heads (1) nature of the disease, (2) nature of the radiation effect, (3) indication, (4) effect on the patient, (5) dosage, (6) radiation technic (7) precautions against undesired radiation effects, (8) best time for radiation therapy, (9) details of the radiation effect (10) by-effects, (11) accessory treatment and (12) contraindications. This is a really valuable work which can be highly recommended.

Textbook of Abnormal Psychology By Roy M. Doreus, Associate in Psychology, Johns Hopkins University, and G. Wilson Shaffer, Psychologist, Sheppard Enoch Pratt Hospital, Towson, Maryland. Cloth. Price \$4. Pp. 389 with illustrations. Baltimore: Williams & Wilkins Company, 1934.

Periodically textbooks on the subject of abnormal psychology appear. A few of them can be considered adequate but most of them are impossible. The present volume seems to be of the first class, and it covers the usual topics dealt with in books of this kind: first disorders of the various mental functions such as judgment, thought and motor activity; and, second, gross pathology of the personality as manifested in sensory neuroses and feeble-mindedness. Such a book as this written for the student of psychology rather than the psychiatrist is bound to be oversimplified and the discussions of mental diseases repeat what is found in the usual psychiatric textbooks. Long case histories are given which serve to exemplify in rather adequate fashion the chief features. To commend this book are its readability and the careful manner in which it has been put together. The chapters discussing motor disorders and interpreting disorders of the mental sphere present new points of view and for this reason may be found to be stimulating to those dealing with psychiatric problems although some of the material presented is of questionable significance. The fact that these authors stress the fact that a competent medical man is needed to diagnose and treat psychologically abnormal states is highly commendable. Except for those portions dealing with individual mental disorders the book should prove to be of much interest to psychiatrists.

Problèmes théoriques et pratiques de la transfusion sanguine. Dix leçons. Indications, groupes sanguins, accidents, technique, organisation, hémothérapie, phylactotransfusion, immunotransfusion. Par Armand Tzanek, médecin des hôpitaux de Paris. Paper. Price 3 francs. Pp. 217 with 34 illustrations. Paris: Masson & Cie, 1933.

The author considers the general indications for blood transfusion. In his experience the blood groups are permanent for each individual but careful and repeated testing is necessary to avoid error. When reactions have occurred further tests have usually shown that some technical error was made. The various causes of complications following transfusions are considered. The technic usually preferred for transfusions is described as well as a number of alternate methods. The citrate method of

indirect transfusion is given preference. Technical difficulties are considered and methods of avoiding them. The method of organization of donors in large and small centers of population, with a description of their card of identification is described. The various conditions for which blood transfusions are used such as general infections for which specific and nonspecific antibodies may be of value, are included. The amount of blood in severe shock must not be too large but in severe hemorrhage multiple and massive transfusions may be necessary. A summary in the form of twenty-eight aphorisms is particularly worth while. The author has produced a clear and concise work, emphasizing the tremendous value obtained from properly performed and correctly indicated blood transfusions.

Medicolegal

Malpractice: Volkmann's Contracture Following Fracture—The plaintiff, 3 years old, fractured his arm just above the elbow joint. The defendant reduced the fracture and treated it, but a Volkmann's contracture followed. The patient, by his next friend, sued, charging negligence on the part of the defendant in that he flexed the forearm so acutely as to impair the circulation, tied too tightly around the wrist the bandage that was carried around the neck to support the arm across the chest, and left that bandage so long that sores developed, injuring the ulnar nerve and neglected to discover and treat the sores that developed. The defendant physician contended that the condition of the plaintiff's arm was due to an injury to the brachial artery at the time of the fracture and that it could not have been prevented by the most skillful treatment. The trial court, however, gave judgment for the plaintiff. The defendant appealed to the Supreme Court of Michigan.

The trial court permitted a witness for the plaintiff to testify, on the basis of a hypothetical question that acute flexing of the forearm for too long a time, under the conditions stated by the plaintiff, would produce certain results. To the question and answer the defendant noted an exception claiming that to answer the question was an invasion of the province of the jury. The appellate court held to the contrary. The witness was properly permitted to testify that certain conditions would, might or could produce certain results. He was not asked what did produce the results complained of by the plaintiff. That was the question for the jury to determine. The defendant physician complained further that the court allowed the plaintiff's counsel to ask one of the defendant's medical expert witnesses whether Scudder said¹ that an arm should be taken down if after a fracture such as that from which the plaintiff suffered swelling and discoloration occur. Swelling and discoloration had occurred in the present case according to the claim of the plaintiff, and the defendant had not taken the arm down. The defendant complained therefore, that even though his medical expert witness was not required by the court to state what Scudder said the asking of the question alone had prejudiced the defendant's case, because it suggested that Scudder did not approve of the treatment the defendant had given. But said the court the witness brought on himself the question propounded by the defendant's counsel when the witness volunteered information not required by any question of the plaintiff's counsel concerning the treatment recommended by Scudder.

The defendant complained that the verdict was against the great weight of the evidence and was excessive. But the Supreme Court held to the contrary. The defendant produced several expert witnesses and the plaintiff called only one. The proof of the controlling fact in the case however did not depend on professional testimony. All witnesses agreed that the condition of the plaintiff's arm was caused by impairment of the circulation and as to the possible causes of such impairment it was either the defendant's treatment or an injury to the brachial artery at the time of the fracture. The claim of an injury to the artery was supported by the defendant's own

¹ Probably in Scudder's *Treatment of Fracture*, ed. 10 Philadelphia: W. B. Saunders Company, 1926.

testimony that after he had reduced the fracture he could not feel the radial pulse. On his testimony, his medical experts based their opinions that the artery was injured at the time of the fracture and by the fracture. The plaintiff's father, however, who was present when the fracture was reduced, testified that the defendant told him that he could feel the radial pulse. If there was a radial pulse, the artery was not injured at that time and the impairment of the circulation must have been caused by the defendant's treatment. So, said the court, on this vitally important question the only testimony was that of the defendant and of the plaintiff's father. No expert witness testified that the treatment shown by the plaintiff's testimony was proper. In fact, said the court, even laymen would know that it was not.

All the medical experts agreed that the condition of the plaintiff's arm and hand was permanent. The muscles of the forearm were atrophied and he had what is known as a claw hand, without any sense of feeling except partial in the thumb. The arm would never be of any use to him. He must carry this humiliating deformity with him throughout his life. He endured intense pain and suffering for many weeks after the injury. For these reasons, the court did not regard the verdict of \$8,750 as excessive.

The judgment of the trial court in favor of the plaintiff was affirmed.—*Van Der Bie v Kools (Mich.)*, 250 N W 268

Accident Insurance "Poisoning" Defined.—The life of the deceased was insured by the appellant insurance company by a policy providing double indemnity if she died by accident other than "poisoning, bacterial infection, illness or disease of any kind." She died from unconsciously and involuntarily breathing carbon monoxide fumes emanating from a natural-gas heater. In the suit that followed the refusal of the insurer to pay double indemnity, the insurer contended, on appeal, that death from inhaling carbon monoxide is death from poisoning and as such exempted the insurer from double liability. The beneficiary under the policy, however, contended that death from the accidental inhalation of gas that results in fatal asphyxiation is not death from poisoning, and that the word "poisoning," as commonly used, does not include asphyxiation through the involuntary, accidental and unconscious inhalation of poisonous gases or fumes. The use of the word "poisoning," said the beneficiary, rendered the double indemnity clause ambiguous and made it mandatory on the court to give it the construction most favorable to the insured.

That the death of the insured was accidental was admitted. The sole question presented was whether it was within the exception in the policy that relieved the insurer from liability if the death of the insured resulted from "poisoning." The word "poisoning" in the policy, said the court of appeals of Texas, Amarillo, can hardly be said not to have been intended to include poisoning by gas. The meaning of the word "poisoning" is not so doubtful as to call for the application of the rule of strict construction in favor of the insured when the meaning of a policy is obscure. The courts have frequently passed on policies containing exceptions saving insurers from liability in cases of death from "inhaling gas or taking poison." With practical unanimity they have held that the words "inhale" and "take" import only voluntary or intentional inhalation or taking. In the present policy, however, the exemption of the insurer from double liability is contingent, not on "inhaling poison" or on "taking poison," but simply on "poisoning." The use of the word "poisoning" alone imports an intention to include any involuntary taking or inhalation of poison and to relieve the insurance company from liability. Judgment was rendered in favor of the insured.

On a motion for a rehearing, the beneficiary under the policy contended that the broad interpretation given by the court to the word "poisoning" might be made the basis for a claim that death from any poison was a "poisoning" as death from typhoid fever contracted through drinking water or ordinary blood poisoning. The court in overruling the motion restricted its construction of the word "poisoning" to the circumstances of the present case where a substance generally known as poison was introduced into the body and directly caused death without any intervening cause.—*United Fidelity Life Ins Co v Roach (Texas)* 63 S W (2d) 723

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- *Calcium and Phosphorus Studies. VI. Observations on Treatment of Late Rickets with Viosterol Based on Study of Twenty Three Cases. D H Shelling and Katharine B Hopper Baltimore —p 61

Treatment of Rickets with Viosterol—Shelling and Hopper state that twenty-two of twenty-three patients having late rickets treated with viosterol were cured completely. The one exception was a 10 year old girl who was treated with a moderate daily dose of viosterol for only forty-five days. The greater prevalence of rickets among Negro children is evident from the fact that, in their series, twenty-one were Negro and only two were white. In one of the white children the rickets was a complication of celiac disease. Some of the children received usual amounts of vitamin D before viosterol therapy while others had not received previous therapy. The usual amounts of vitamin D, even when administered over a long period produced only partial healing but when larger amounts of viosterol were administered healing occurred fairly rapidly and completely. In none of the patients treated with fairly large doses of viosterol was clinical evidence of toxicity noted, even when the therapy was continued for more than a year. In seven of the cases osteotomy or manual osteoclasia was performed for the correction of rachitic deformities before or during viosterol therapy. Complete union at the site of operation occurred in all cases. The corrective results, however were much better in the cases in which rapid healing was induced by larger doses of viosterol, since the rigidity which the legs thus acquired enabled them to withstand the weight of the body without yielding. The authors discuss the factors that enhance or hinder the activity of viosterol in late rickets and call attention to the inadvisability of using vitamin D preparations in renal rickets.

Gonadotropic Hormone and Estrin in Toxemias of Pregnancy—The Smiths analyzed forty-six serums and forty-four twenty-four hour specimens of urine from forty-two women in the last third of pregnancy for their content of the gonadotropic hormone (prolan) and estrin. Of these women fifteen were normal twenty-two had toxic symptoms without convulsions and five had eclampsia. One of the patients having toxic symptoms was definitely nephritic and showed normal levels of prolan and estrin. In no case diagnosed as toxemia or eclampsia were both estrin and prolan within the limits of values found in the normal women at the same period of gestation. In a number of the toxemic women there was unquestionably a nephritic element. All but one of twenty-six toxemic and eclamptic patients or 96 per cent showed excessive amounts of prolan in the urine and serum and eighteen of them or 69 per cent presented subnormal levels of estrin. The urines and serums of one toxemic patient were analyzed monthly from the second month of pregnancy to term. During the sixth month an abnormal increase in prolan and a decrease in estrin appeared which continued with fluctuations until delivery. This patient did not develop toxic symptoms until the eighth month. A quantitative imbalance of these two hormones due to excessive amounts of prolan and less consistently to subnormal levels of estrin is typical of the toxemias of late pregnancy.

Air Embolism Complicating Thyroidectomy—Larson and Nordland believe that in a thyroidectomy it is strongly advisable to ligate securely any vessels of size before they are divided, and at the completion of the operation to have the patient cough or strain, so that bleeding points may be detected and secured. After air embolism has taken place, artificial respiration and cardiac stimulation with digitalis or caffeine is indicated. The use of epinephrine administered directly into the heart is no doubt of considerable aid. As indicated in experimental work, it is theoretically possible to aspirate air from the right ventricle and this procedure when followed by intracardial injection of epinephrine should be the treatment of choice. The prognosis depends directly on the amount of air aspirated.

Relationship of Thyroid Disease and Pancreatic Function—Hinton and his associates observed both from animal experiments and from the clinical cases that there is a definite interrelation between the thyroid and the digestive processes. Dogs with their pancreatic ducts ligated, and without medicine develop colloid goiters with a high iodine content in the gland, and progressively lose weight and usually die within from six to twelve weeks. The administration of potassium iodide, tyramine or diiodotyrosine will result in death in animals that have their pancreatic ducts ligated within from ten days to three weeks, whereas animals without their ducts ligated tolerate these medicines without ill effects. Dogs that are given thyroxine, intravenously, after ligation of the pancreatic ducts maintain their weight and clinically are in a good state of health over a long period and rarely die if thyroxine is administered regularly. From clinical observations of typical cases of hypothyroidism a much more satisfactory response was found to the intravenous use of thyroxine, with thyroid by mouth, than in cases treated with thyroid without the intravenous use of thyroxine. In the cases of undersecreting thyroids with abdominal pain it is rarely possible to relieve the symptoms by the oral administration of thyroid but the response is most favorable to thyroxine intravenously and to thyroid by mouth. The cases of peptic ulcer treated by the authors were markedly relieved symptomatically as a result of thyroxine and thyroid therapy. They do not claim that this is a cure for ulcers, but from their limited clinical experience it has proved quite satisfactory. This may be explained on the basis of a chronic pancreatitis associated with the ulcer. Chronic

pancreatitis is the only real indication for surgical intervention in patients suffering from ulcers, and they feel that there is a pancreatic involvement in a much higher proportion of these cases than has generally been admitted.

Treatment of Myasthenia Gravis with Glycine and Ephedrine—Boothby states that, of twelve patients suffering from myasthenia gravis treated with ephedrine and glycine, ten have shown definite improvement, and four of these have shown marked improvement. Two did not respond to treatment except that the progress of the disease was apparently arrested, one of the two died from causes not directly attributable to the myasthenic syndrome. The author believes that by the careful use of either ephedrine or glycine, and more often of the two, the condition of most patients having myasthenia gravis can be improved sufficiently to permit them to return to work or at least to enjoy a useful life. Time alone will tell whether this improvement can be maintained. The disease occurs much more frequently than is generally supposed.

Rheumatoid Arthritis Cultures of Synovial Fluid and of Tissues—Blair and Hallman summarize the results of 232 cultures of synovial fluid and tissue made during the past three years. In a series of fifty-seven cultures of synovial fluids and tissues from chronic multiple arthritis (fifty five from rheumatoid arthritis and two from Still's disease), a total of forty-one (74.5 per cent) remained sterile and fourteen (25.4 per cent) yielded positive cultures. The micro-organisms obtained in the positive cultures included streptococci diphtheroid bacilli gram-positive cocci incapable of growth on subculture and an occasional gram negative bacillus associated with the aforementioned bacteria. In a series of 175 cultures of synovial fluids and tissues from a variety of chronic infectious and noninfectious conditions of the joint other than rheumatoid arthritis, 142 (81.1 per cent) were sterile and thirty three (18.8 per cent) were positive. The positive cultures included *Staphylococcus aureus* indifferently streptococci gram positive cocci incapable of growth on subculture and diphtheroid bacilli. No direct etiologic significance is attached to any of the organisms obtained in this series. It is felt that at the present time no specific bacteriologic agent may be considered to have been demonstrated as the etiologic cause of rheumatoid arthritis particularly in view of the multiplicity of results and the lack of general confirmation of any one report.

Insulin and Sugar Tolerance in Thin People—Blotner discusses the effect of insulin on sugar tolerance in twenty five thin persons who gained weight by the use of this drug. Tests were made before treatment in nine cases, after one to twelve weeks of continuous administration of insulin in sixteen cases and finally from three days to two years after the

cessation of administration of insulin in all cases. Three types of curves for sugar tolerance were obtained. In one the curves for blood sugar were normal, and the urine remained sugar-free during all the periods of observation. In the second the curves for blood sugar were normal during the various periods of study, but during the period of administration of insulin glycosuria appeared, usually one or two hours after the ingestion of the dextrose. In the third type the curves for blood sugar were normal either before or after the use of insulin, but during the period of treatment with insulin there developed a considerable increase in the concentration of the blood sugar in one half or one hour after the ingestion of dextrose; this was associated with glycosuria which usually appeared in one or two hours. The cause of the temporary decrease in tolerance induced by insulin is a matter of speculation. The author suggests that the type of tolerance associated with glycosuria and normal curves for blood sugar is due to a decreased renal threshold, and the type associated with glycosuria and hyperglycemia to either an increased absorption of sugar from the gastrointestinal tract or a temporary suppression of pancreatic function. Regardless of the cause of the glycosuria and hyperglycemia encountered, the observation was of no practical significance, since the sugar tolerance invariably returned to normal shortly after insulin was omitted. Decrease in tolerance to the customary diets employed by these patients while they were taking insulin for the purpose of gaining weight was not observed even though the diets contained abundant amounts of carbohydrate.

Visual Sensation Produced by Roentgen and Radium Rays—Gifford and Barth found that roentgen and radium rays are visible to the dark adapted eye. There is a difference in their visibility in that the roentgen rays may be localized accurately and that small radiopaque objects may be recognized in their light. The radium rays produce only a vague luminous sensation which cannot be correctly localized. Examination of the vision by means of roentgen rays gives some information as to the function of the peripheral retina in patients with opaque media. It does not however serve in judging of the macular function and in certain patients the results are unreliable. Care must be taken to avoid injury to the eyes especially in the lenses are clear and not more than from 10 to 15 milliamperes of current should be employed for not more than three

minutes. In patients having cataract, this amount may be exceeded. It seems probable that the sensation produced by roentgen rays is due to a direct photochemical effect on the rods.

Prevention of Spontaneous Retinal Detachment—Lindner points out that, if clinical experience is considered in the light of mechanical experiments, the prevention of detachment must consist in the prevention of the retinal tear. If the vitreous is mostly liquefied or detached and shrunken into a small remnant behind the lens, the presence of the flap hole alone is sufficient to cause detachment when the eye moves. It is self evident that the spread of spontaneous detachment can be stopped in most cases by simple immobilization of the eyeball with the aid of suitable glasses. This often prevents the formation of secondary, sometimes invisible, holes and thus assures a good prognosis for operation. The author believes that at some future time one will be able to detect the eyes in which the danger of detachment is imminent, and in these one would not hesitate to perform an operation. At present he is trying glasses which are only slightly roughened around the clear pupillary area, so that the patient sees through the other parts of the glass, but vision is somewhat foggy. They are less conspicuous than other types of spectacles.

Formation of Pure Cholesterol Gallstones—The experiments of Weiser and Gray on the mechanism by which precipitated cholesterol may be collected into a unified coherent mass show that 1 Precipitation of cholesterol in the gallbladder is in itself altogether inadequate to account for the formation of pure cholesterol concretions. 2 Experimental observations have been made which furnish the basis of a mechanism to account for the formation of such concretions during biliary stasis resulting from anatomic or physiologic abnormalities. 3 By the proposed mechanism, gallstones have been synthesized which simulate the natural concretions in both macroscopic and microscopic appearance and in properties. 4 Particular attention has been called to the importance of fat in the formation of pure cholesterol concretions both as a collecting agent for the minute particles of precipitated cholesterol and as a solvent that is responsible for the growth of interlacing crystals into a concretion.

Experimental Studies in Amyloidosis—Grayzel and his associates found that amyloidosis can be produced in all albino mice by subcutaneous or intramuscular injections of a 5 per cent aqueous suspension of sodium caseinate. The earliest amyloid appears within the fixed and wandering cells of the reticular system. As these cells disintegrate extracellular amyloid appears, grows in amount and finally replaces the parenchyma of the organ involved. Amyloidosis is probably the result of an endogenous protein metabolic disturbance. When the rate of formation of these catabolic products exceeds the ability of the tissues to dispose of them amyloid appears. With the present technique amyloidosis cannot be produced in albino rats. Except in albino mice showing precursors or early evidences of amyloidosis no spontaneous resorption of amyloid in definite cases of amyloidosis was observed. Albino mice given a preparation of powdered whole liver in their diet showed resorption only when the degree of amyloidosis was no more than moderate. No retrogression of the disease was noted in advanced cases. Comparative studies indicate that a cell

balanced, thoroughly adequate diet exerts a retarding influence on the production of amyloidosis. The addition of a preparation of desiccated powdered whole liver to the stock diet results in delay in the formation of amyloidosis. Inadequate or deficient diets do not accelerate the development of amyloidosis. Mice fed a synthetic and the so called stock diet to which vitamins A and B were added showed definite evidence of retardation of the production and formation of amyloidosis.

Use of Cow's Horn in Internal Fixation of Fractures

—A year ago Fowler began the use of cow's horn as an internal fixation material in fractures that required open reduction because of extensive interposed tissue. The bones involved were one clavicle, two humeri, one radius, one femur, three ulnas and one tibia. After the incision and exposure of the fracture, a hole is drilled through the cortex from 1 to 3 inches distant from and reamed obliquely toward the fracture. The medullary tissue is drilled or reamed from 1 to 3 inches each way at the fracture to receive the corticomedullary horn splint. While the bone fragments are held in line, the splint rod of horn is passed or lightly driven through the cortex along the medullary canal beyond the fracture from 1 to 3 inches, depend-

ing on the size and length of the bone involved. The surplus horn protruding is cut moderately close to the cortex. The subcutaneous structures are approximated and, if necessary to close any dead spaces, a few fine plain gut sutures are inserted. The skin is closed with dermal sutures and a plaster cast is applied as in a simple fracture. All nine fractures united promptly with what appeared to be a superabundance of callus. No complication occurred. In the first patient, operated on a year ago, the end of the horn in the ulna was palpable under the skin over the olecranon for a period of six months.

Treatment of Fractures of Upper End of Humerus—Howard and Eloesser point out that in fractures of the upper end of the humerus one has control of the short fragment by virtue of the long head of the biceps bridging the fragments and the remaining untorn periosteum. Clinical experience indicates that when the arm is abducted, the pull of the abductor muscles makes approximation difficult to obtain and still more difficult to preserve. Accurate approximation can be obtained and maintained by downward traction, a fact demonstrated on the phantom model and by clinical experience. The integrity of the long head of the biceps tendon is necessary for the use of this method. Reduction under local anesthesia for fractures of the upper end of the humerus may be accomplished by the

following maneuver With the patient sitting upright, supporting the injured arm across the body with the opposite hand, a folded face towel is placed over the forearm just below the elbow A 4 or 6 inch heavy muslin bandage is looped over the towel and tied in a sling, so that its lower end hangs from 8 to 12 inches from the floor An assistant grasps the wrist of the injured arm and, bringing the forearm at right angles to the body in the sagittal plane, maintains right-angled flexion of the elbow The surgeon then places one foot in the sling, grasps the upper arm with both hands below the line of fracture, and slowly and steadily increases the amount of pressure on this foot The two hands grasping the arm below the fracture are used to force the upper end of the distal fragment laterally, anteriorly or posteriorly, as required by the displacement For the dressing, a small pad is placed in the axilla and along the arm The forearm is held flexed by a sling, while the arm is loosely bound to the body, the elbow is left free to allow the weight of the arm to act as a traction force

Correction of Severe Equinus Deformity—Mayer presents a new method of overcoming severe equinus deformity in cases of congenital clubfoot or of paralytic equinus, which consists of driving a nail or wire through the posterior part of the os calcis, by means of which the os calcis can be firmly grasped The nail is included in the plaster-of-paris cast applied at the time of manipulation A manipulation period of six weeks is usually sufficient to correct the most marked degree of equinus Thus far the author has employed this method in fifteen cases The age of the patients ranged from 9 months to 4 years In each instance the patient had been under treatment at the hands of a skilled orthopedic surgeon who had been unable to correct the equinus deformity Two of the cases were paralytic in origin, the others were congenital In all complete correction of the deformity has been secured

Correction of Congenital Talipes Equinovarus—To obtain better functional results and shorten the period of disability in congenital clubfoot, Curtis and Muro performed the following operation on fifty-one children and on sixty-nine feet A short incision is made in front of the external malleolus on a line with the tubercle on the anterior portion of the os calcis and extending over the cuboid The peroneus longus and brevis tendons are retracted toward the sole of the foot The short dorsal flexor muscles (extensor brevis digitorum) are separated from their origin on the lateral side of the os calcis and retracted toward the top of the foot, thus giving exposure of the neck of the astragalus, the anterior portion of the os calcis, and the cuboid A small puncture wound is made in the three bones With successively larger curets, all the cancellous bone is removed from the cuboid while from the os calcis and astragalus only the anterior portion is removed The foot is then forcibly overcorrected by manipulation with a Thomas wrench To correct the metatarsus varus and decrease the convexity of the outer border of the foot, manipulation is done over a rectangular bar When visible collapse of the bones is not evident after manipulation the outer shell of the cortical bone of the cuboid and os calcis is split vertically, with scissors to allow collapse If necessary, in older children a section of the outer shell is removed and the articulating surface is not disturbed The dissected muscle is then sutured in place and the skin is sutured with plain catgut The leg is placed in a plaster-of-paris cast extending from the mid thigh to the toes, with the foot dorsiflexed and everted the tibia rotated externally and the knee flexed The first plaster cast is removed at the end of three weeks, reapplied under anesthesia after the foot has been manipulated to the overcorrected position and worn for four months, after which an inside upright and outside T strap brace is applied Physical therapy and muscle education are then carried on to develop the peroneal and dorsal flexor muscles of the foot The brace is worn and muscle education continued until such time as the patient is able to place the foot actively in the fully overcorrected position In summarizing the results of this operation the authors feel that (1) it allows full correction of the clubfoot at an early age (2) it is particularly applicable to the resistant and neglected clubfoot (3) it leaves the foot with a good range of motion and stiffness does not result as from multiple manipulative procedures (4) it shortens the period of treatment and (5) there is no interference with the growth of the bones operated on

Treatment of Common Metatarsal Disabilities.—Rugh uses gas anesthesia, cutting the plantar-flexor tendons with a long shanked, narrow-bladed, sharp tenotome An assistant holds the foot and makes pressure against the ball The little toe is first pulled straight, the tenotome inserted on the outer side of the base of the toe and the tendon cut The blade is pushed forward and the tendons of the fourth, third and second toes are cut in the same manner The tenotome is withdrawn and pressure is made with a pledget of gauze over the puncture to control the bleeding The other foot is similarly treated It is now possible to dorsiflex the toes when they are held straight with the fingers and, when the patient stands barefooted, the toes lie out straight A small dressing is held in place with adhesive plaster and suitable stockings and shoes are put on After a rest of a few minutes the patient may be sent home and advised to continue walking about In three days the dressing is removed, the feet are soaked daily in hot water and the toes are drawn strongly by the fingers into dorsal flexion to prevent recontraction Proper shoes of sufficient length are fitted to the feet In a month or six weeks the corns disappear and later the calluses also, and the feet function painlessly The test for contraction is inability to dorsiflex the straightened toes with the fingers when the foot is held at right angles to the leg, by upward pressure on the ball of the foot Section of the plantar flexors relieves the flexion and dislocation, does not incapacitate the patient and, when proper shoes are worn, gets rid of the corns and calluses The author corrected three cases of Morton's toe with the same treatment

Correction of Long Standing Bony Deformity at the Knee—Whitman reports two cases that showed solid bony ankylosis of the knee joint, with the tibia fused at a right angle to the femur The first patient was a child of 11 with ankylosis of four years, while in the other one, a man of 55, the deformity dated back forty years Removal of a bony wedge sufficient to correct the angulation would have caused great shortening of the limb as well as running grave risks of compromising the circulation It occurred to the author that the principle of lengthening short limbs—gradual alteration of the structure of bone—was applicable In the first case two 3 inch incisions curving downward were made lateral to the patella The upper surface of the femur was exposed and the periosteum stripped back A Gigli saw was then passed across the bone, subperiosteally, the patella sawed through its attachment to the femur, and the saw passed curving down and backward in such a manner as to approximate the original outline of the femoral condyles The flexion deformity was then easily reduced to an angle of 135 degrees A plaster spica was applied Within the next eight days the plaster was wedged The next day a roentgenogram taken after manipulation and correction to 170 degrees showed full correction Eight days later the patient began bearing his weight in a plaster cast and was discharged on the following day He is now walking without apparatus and his leg is fully extended on the thigh The other patient's knee is ankylosed at an angle of 160 degrees, which enables him, with a high heel in an ordinary shoe, to walk without apparatus—the first time in forty years that he has had his foot on the ground The deformity might have been fully corrected had the posteriorly projecting portion of the tibia been removed However, the extremity was converted from a useless to a weight bearing one which gave its owner satisfaction

Treatment of Surgical Tuberculosis with Splenic Extract—In order to determine the effect of splenic extract in tuberculosis Barr selected twenty children each with acute tuberculosis of the hip or spine Ten were used as experimental subjects treated with splenic extract and the other ten as controls Each patient was paired with a control as carefully as possible for age, duration and extent of the disease prognosis and so on There were no cases of amyloid disease or secondarily infected sinuses in either group Of the ten pairs, seven were considered to have made almost identical progress and were in approximately the same local and general physical condition In one case the child fed splenic extract was found to be much better generally and locally than the control, while in two cases the reverse was true i e the control child seemed to have done better than the one fed splenic extract The author feels justified in discontinuing the use of splenic extract in such cases until further proof of its usefulness is adduced

Blood Lipids After Ingestion of Fat—Chaikoff and his associates studied the normal fat metabolism in twelve young adults, ten men and two women, varying in age from 17 to 39 years, and investigated the metabolism of a patient presenting cutaneous xanthomas in the following respects: (1) the levels of the blood lipids in the postabsorptive state during a prolonged period of observation; (2) the effect of a short fast on the blood lipids; (3) the quantitative relation of total fatty acids, free cholesterol and ester cholesterol of the blood; and (4) the response of the blood lipids to ingested fat. Whole blood lipids were determined by means of oxidative procedures in the twelve normal subjects in the postabsorptive state. The influence of the ingestion of 100 cc of olive oil on the blood lipids in normal subjects was determined. Marked variations in the response of the fatty acids in different individuals were observed. The maximal increase in the fatty acid content of the blood during an observation period of ten hours was 35 per cent. In six out of the seven normal subjects so studied the ingestion of fat had no appreciable effect on the cholesterol level of the blood. The limitations in the use of the curve of alimentary lipemia as an index of altered fat metabolism are discussed. The level of the blood lipids in the patient having cutaneous xanthomas was followed for fourteen weeks. During this period the total lipid values fluctuated from a minimum of 1,160 mg to a maximum of 2,180 mg per hundred cubic centimeters. The main constituent affected in this rise was the fatty acid portion, which throughout the period of observation constituted from 72 to 79 per cent of the total lipids. The total cholesterol portion varied from 322 to 470 mg per hundred cubic centimeters of whole blood and constituted from 21 to 28 per cent of the total lipids. On two occasions the cholesterol fraction in relation to total lipids was definitely below the lowest value found in the case of the normal subjects. The proportion of cholesterol in the esterified form was somewhat higher than that obtained in normal subjects. The response of the blood lipids to the ingestion of 100 cc of olive oil was determined on four different occasions in the patient presenting xanthomatous tumors. No abnormality as compared with normal subjects was observed. In three experiments no appreciable rise in the blood fatty acids was noted whereas in a single instance a delayed rise of a prolonged nature was obtained. The cholesterol level was not altered by the absorption of fat. The nature of the lipemia in xanthomatosis is discussed.

Pain in Exercising Muscle During Anoxemia—Kissin induced a progressive generalized anoxemia in eight normal subjects by having them rebreathe the air from a 20 liter tank connected in series with an 8 liter spirometer. The

accumulation of carbon dioxide was prevented by passing the expired air over soda lime. As a control, each subject, while breathing room air, repeated his exercise at the same rate and as nearly as possible in the same position as in the anoxemia experiments. The author observed that generalized anoxemia without ischemia can induce pain in an exercising skeletal muscle. Within certain limits the severity and rapidity of onset of the pain varies with the degree of anoxemia and with the rate of exercise of the muscles involved. The pain appears to be due to accumulation of products of muscular metabolism that require oxygen for their disposal.

Antistreptolysin in Blood Serum in Arthritis—According to Myers and Keefer, in proved hemolytic streptococcus infections the blood serum generally contains antistreptolysin in higher titer than in normal persons or than in patients with infections caused by other microorganisms. Patients with acute rheumatic fever, who have had a streptococcus infection present antistreptolysin titers in their sera comparable to those observed in scarlet fever, erysipelas or acute follicular tonsillitis. Rheumatoid arthritis and certain other forms of joint disease are not accompanied by an increase in the antistreptolysin titer of the blood serum. Antistreptolysin was shown to be an antibody separate and distinct from streptococcus antitoxin or the antibodies responsible for streptococcus agglutination. Antistreptolysin is not related to the skin sensitivity to the nucleoprotein of *Streptococcus scarlatinae*.

Microchemical Detection of Lead—Harwood and Brophy describe modifications of the Fairhall method of the hexanitrite test for the detection of lead. At least 5 cc of cerebrospinal fluid is evaporated to dryness on the water bath in a silica crucible of about 25 cc capacity. To the residue is added about 0.5 cc of redistilled nitric acid dropwise so as to saturate all the residue. The contents of the crucible are again evaporated to dryness. The addition of a few drops of nitric acid, followed by evaporation to dryness, is repeated until only a white crystalline residue remains. About 2 cc of redistilled hydrochloric acid is added, rinsing down the sides of the crucible. This is again taken to dryness, in order to destroy any excess of nitric acid or of nitrates. The inorganic residue is then dissolved in about 2 cc of twice normal hydrochloric acid and is transferred to a 15 cc Pyrex centrifuge tube. The crucible is rinsed out with redistilled water bringing the contents of the centrifuge tube to a volume of about 6 cc, then 1 cc of a saturated solution of ammonium chloride is added and the solution is neutralized until just acid to methyl orange by the use of about fifth normal ammonium hydroxide. A drop of 2 per cent cupric acetate solution is then added and hydrogen sulphide is passed into the solution in a slow stream for about ten minutes. The sulphides are centrifuged and washed at least three times by decantation, each time 2 cc of the solution (0.01 normal hydrochloric acid saturated with hydrogen sulphide) being used. The washing must be thorough and the liquid must be drained completely from the sulphide precipitate each time. Two drops of redistilled nitric acid is added and the tube is covered with a short Pyrex test tube and placed in boiling water until the precipitate is completely dissolved. About one third of the solution so obtained is drawn into a capillary pipet and is evaporated to dryness on a microscope slide. About 10 cmm of a 1 per cent solution of sodium acetate is then added. The material is again evaporated to dryness giving a rim of about 4 mm in diameter in which the greater part of the salts are concentrated. The slide is then chilled on ice. Not more than 5 cmm of a 10 per cent solution of acetic acid and a tiny crystal of potassium nitrite are added to the center of the residue. The nitrite solution is evenly distributed inside the rim of salts by means

of a glass needle. A cover glass is placed on the preparation and the nitrite solution is allowed to diffuse slowly to the outer edge. This allows the small dark brown squares and cubes of lead hexanitrite to form under optimal conditions. These crystals are usually found at the outer rim scattered among the sodium and copper acetate crystals.

Agglutinins for Typhoid Organisms in Blood Serum in Poliomyelitis.—In ascertaining the relative agglutinin titer for colon paratyphoid organisms of poliomyelitis patients, Toomey found that the convalescent serums of fifty five of eighty eight patients showed an increase in agglutinin titer or agglutination in the higher suspensions than was present in the same comparative dilutions of serum and antigen from patients in the acute stage (group I). The convalescent serums of thirty one patients gave about the same agglutinin titer as did the serums obtained during the acute stage (group II), while the serum of two patients showed a slightly better titer when obtained in the acute stage as compared with convalescent serum and antigen (group III). Of seventy four patients with diseases other than poliomyelitis, sixty-five showed no comparative increase of the agglutinin titer. Three patients having scarlet fever showed a slight increase, while six others (8 per cent) showed marked increases in the colon agglutination titers in the specimens obtained in the convalescent stages. These increases occurred in patients who had received horse serum in the form of diphtheria or erysipelas antitoxin. This fact could easily account for the increase in agglutinin. The sameness of agglutinin reactions obtained in these specimens with serums from the acute and from the convalescent stages was in decided contrast to the difference in reaction obtained with serum from patients in the acute and in the convalescent stages of poliomyelitis against the same organisms. Twelve monkeys that received injections of vaccine suspension and filtrate showed a marked increase in the agglutinin titer of their blood serum against the eight organisms (paratyphoid A and B 208 209 1 11, 14 and 42) used when the blood serum was tested immediately after injections of vaccine filtrate and before the injection of the virus of poliomyelitis. Poliomyelitis developed in all but one animal. Eleven specimens of blood serum obtained from the animals within the first few days after the disease began showed a marked drop in agglutinin titer of the serum for the various typhoid organisms used. Specimens obtained when animals were in the moribund state rarely contained any agglutinins though in the 1:20 and 1:40 dilutions a clearing of the suspensions without any deposit of organisms on the bottom of the tube was found sometimes.

Cancer of the Stomach.—Lahey and Jordan state that, following the removal of the distal portion of the stomach and anastomosis of the jejunum to the remaining gastric stump, a long loop of jejunum may be brought up over the transverse colon and anastomosed to the cut end of the stomach (anticoilic Polya anastomosis) or the transverse colon may be brought out on the abdominal wall and an incision made in its posterior root, through which is passed a loop of jejunum to be anastomosed to the cut end of the stomach. The point that they wish to suggest in connection with this is that after an opening has been made in the posterior leaf of the transverse mesocolon the jejunum, where it emerges from its retroperitoneal portion, is put on the stretch, the ligament of Treitz demonstrated and the ligament cut by scissors up to its root. The incision of the ligament of Treitz then makes possible the transplantation of the proximal loop of jejunum entirely above the transverse mesocolon so that, after the anastomosis is complete, the proximal section of the jejunum that is sutured to the lesser gastric curvature is entirely above the posterior leaf of the transverse mesocolon and but a single loop of intestine, the distal loop of the jejunum that runs from the greater curvature down into the peritoneal cavity, emerges through the rent in the transverse mesocolon. This makes possible the approximation of the rent in the transverse mesocolon about a single loop of intestine, preventing the danger of hernia and making the course of the proximal loop of intestine an unangulated one. The authors used this method of dealing with the proximal jejunal loop in gastric resections in more than twenty cases. It has proved a satisfactory one.

Pain of Peptic Ulcer.—Rivers points out that the clemat-cut syndrome generally accepted as being diagnostic of peptic ulcer usually indicates an uncomplicated ulcer. When the pain of gastric ulcer shifts definitely to the left, slightly upward or to the back, when the pain of a duodenal ulcer radiates toward the right, upward over the area of the liver or through to the back, when the pain of a gastrojejunal ulcer extends downward or through to the back, one usually can correctly assume deep penetration or partial perforation of the lesion. The presence of two distinctly separated areas of pain, especially if the pain is projected from elsewhere to these two widely separated areas, frequently is indicative of two peptic lesions, such as associated duodenal and gastrojejunal ulcer, or such as gastric ulcer high on the lesser curvature associated with a perforating duodenal ulcer. Uncomplicated peptic ulcer probably indicates its presence as a visceral phenomenon, which asserts its presence over the splanchnic nerves. The radiating pains of perforating peptic ulcers are in all probability the results of direct stimulation of the intercostal branches of sensory spinal nerves. It is conceivable that the distortion of the approved syndrome of ulcer in such instances is influenced by the accumulation of impulses of varying intensity that are carried over both the splanchnic nerves and the spinal sensory system.

Nonsurgical Treatment of Diabetic Gangrene and Infections of the Lower Extremity—Dillon and Hitzrot remove all pressure from the local lesion and this usually means that a shoe cannot be worn. In all but the mildest cases the patients should go to bed. If the patient sits up the foot should be kept at the level of the thigh. The leg should not hang down. Circular garters and rolled stockings are to be avoided. The foot should be kept warm. This is usually accomplished best by a cradle and electric light, the temperature of the air being kept between 90 and 95 F. The electric light must be kept well away from the foot, as burns occur easily. Dry heat is usually preferable to moist heat. Warm moist dressings may be used in treating lymphangitis, but lymphangitis usually means that surgery is necessary. Moist dressings may be used to aid in the removal of crusts under which there is infection. Moist dressings, however, usually cause undesirable maceration of the tissues. All salves and ointments are to be avoided, as these only serve to seal up the infection. Likewise all powerful irritants are to be avoided, as the sound tissues are easily damaged. Treating an infected area with surgical solution of chlorinated soda is often useful, but usually in cases in which surgery has been used. Buerger exercises, consisting in cycles of alternately raising and lowering the limb from the horizontal position are useful. The economic consideration is a serious one in these cases. Of the authors' forty-three patients, the average stay in the ward was thirty-four days.

Treatment of Dementia Praecox by Continuous Oxygen Administration—Hinsie and his associates observed five patients who resided continuously for two and a half months in an oxygen chamber at a concentration of approximately 50 per cent oxygen. During this period they received treat-

ments of carbon dioxide and oxygen daily. After each carbon dioxide inhalation attempts, extending over four to five hours were made to establish communicability with the patients. Two of the five patients gained a state of remission, the clinical history of these two patients had indicated a favorable prognosis. A second group of five patients was treated similarly in an oxygen dormitory, except that no attempts to establish communicability were made. None of these showed clinical improvement. A third group of five patients resided in the oxygen dormitory at a concentration of approximately 50 per cent oxygen, without carbon dioxide treatment and without attempts made to establish communicability. None of these patients showed clinical improvement. A fourth group of five patients, living under normal atmospheric conditions and the usual hospital routine was given daily inhalations of carbon dioxide and oxygen. Of this group one patient showed clinical improvement but did not gain a remission. In all patients the arterial oxygen content and oxygen saturation were within normal range before treatment was instituted. The effect of inhalation of 50 per cent oxygen on the arterial oxygen saturation was not dissimilar to its effect on normal persons. The arterial carbon dioxide content of the patients ranged within normal limits both before and after oxygen, and oxygen and carbon dioxide treatments. In the patients treated by oxygen alone there was generally a decrease of from 10 to 15 per cent in the circulating hemoglobin. Except in one instance, the hemoglobin in those patients who received inhalations of oxygen and carbon dioxide did not show a diminution. Chemical studies of the blood showed no effect of long continued oxygen inhalation on the urea nitrogen, uric acid or blood sugar content of venous blood. Basal metabolic determinations varied so much that no consistent conclusions could be drawn. Under various psychologic tests no consistent improvement was observed in the patients who did not gain a remission. Physiologic measurements, involving respiration, pulse and blood pressure, were generally within normal range, both before and after the treatment administered.

Roentgen Diagnosis of Atelectasis—Van Allen and his associates show that the difficulties in the roentgen diagnosis of atelectasis are due largely to two causes: lack of agreement in the definition of atelectasis and lack of pathognomonic signs. The preference of the authors as to terms is stated and some recently acquired facts as to the degree of shrinkage of the diseased section of the lungs in pneumonia as compared to that in atelectasis are introduced. The differential diagnosis of atelectasis is outlined with special reference to the manner of use of the ground-glass lung and of the degree of pulmonary shrinkage. They describe a new sign (ground-glass lung) in which the roentgenogram has the appearance of glass with a

finely ground unpolished surface. Their observations have shown that the shadow of an area of atelectasis—congenital obstructive or compressive, in dog or in man—always exhibits the ground glass roentgen shadow, provided (1) the dosage of x-rays is such as to obtain penetration of the tissues and demonstration of their radioconsistency (which is usually the case with the standard thoracic roentgenogram) and (2) the shadow of the lesion is large enough to permit discernment of its consistency. Many of the common consolidating lesions of the lung that are confused with atelectasis present a distinctly heterogeneous consistency of shadow because of residual air. Some lesions besides atelectasis present ground-glass shadows, but these are usually distinguished from the presence of other signs. In short, the ground-glass sign enters into the diagnosis of pulmonary lesions to the extent that it indicates complete airlessness of the field ordinarily occupied by the lung or of such part of that field as is large enough for the composition of the roentgen shadow to be recognized.

Diffuse Interstitial Calcinosis—Scholz presents a case of diffuse interstitial calcinosis clinically characterized by small, hard, subcutaneous nodules that show a tendency to open spontaneously and to discharge greasy pus, leaving slowly healing ulcers. It may occur in a localized form, involving practically any part of the body, or a diffuse form, which may gradually extend over the entire body. The appearance of the nodules may be preceded or followed by scleroderma-like cutaneous changes, which may become a prominent clinical feature. Roentgenologically it presents characteristic evidence of calcification. The latter is most common in the extremities. Pathologically the condition is characterized by hypertrophy and degeneration of the interstitial connective tissue, with secondary deposition of calcium salts in the fibrous tissue elements. Notwithstanding its characteristic clinical, roentgenologic and pathologic signs the condition probably is not to be classified as a separate clinical and pathologic entity but as an advanced stage of a chronic inflammatory condition that may be the basic lesion common to all the members of the scleroderma group. Necropsy evidence shows that in interstitial calcinosis the calcium salts are deposited only in degenerated fibrous tissue and that muscle fibers, no matter how degenerated they may be, do not contain any calcium. This tends to support the theory that in the dystrophic type of calcification pathologic connective tissue is the sole carrier of the deposited calcium salts.

Rhinologic Treatment of Asthma J N Fishbein Providence—p 5

Rhinologic Treatment of Asthma—Tamponage augmented by diathermy has been found by Fishbein to be the most effective method of treatment. The colloidal silver solution employed passes through the membrane without ill effects and is capable of destroying bacterial life without injury to the tissues. Leaving the tampons in place for about an hour enhances the use of diathermy and the time of treatment is reduced to about fifteen or twenty minutes. The tampon is saturated with the colloidal silver solution and inserted into the middle meatus as far back as possible in the direction of the sphenoid sinus. Preceding this a smaller tampon is inserted high into the olfactory fissure. The indifferent or dispersive electrode is placed on the forehead by means of a head band. The electrode consists of a piece of block tin about 1½ by 6 inches. The two ends of the diathermy tape from the nostrils are attached to one of the poles and the tape from the dispersive electrode to the other terminal. A current of from 250 to 450 milliamperes is employed and left on for about twenty minutes. Many conditions such as acute or chronic infections of the nasal accessory sinuses are benefited. When the patient is found to be hypersensitive to some dust or food an attempt is made at desensitization to the specific substance. When no specific substance is found nonspecific treatment is given consisting of the parenteral injection of a nonspecific protein.

*Congenital Anomalies of Ileocolic Region with Especial Reference to Chronic Manifestations C W Roberts Atlanta Ga—p 301

Pancreatic Lithiasis—Thomason presents a case of pancreatic lithiasis with a history of similar attacks of pain in two members of the family. A brother, operated on three years ago, had had attacks of high epigastric pain, nausea and constipation. He had an extreme grade of movable cecum with partial obstruction of the hepatic flexure and large mesenteric glands. No pancreatic disease was observed. Symptoms were completely relieved by appendectomy and cecopexy. A cousin, a young boy, also had attacks of pain, and at operation an inflamed gallbladder with an enlarged, hard pancreas was found. This boy continues to have occasional attacks of pain. The fact that no calculi were demonstrated in the roentgenograms of the author's patient two and a half years ago suggests that previous attacks (that is, since the age of 5) were due to a recurring pancreatitis, the calculi being a relatively late complication. It is conceivable that developmental defects present in the girl and her brother, and doubtless in her cousin may have been an etiologic factor. In both children, appendectomy and cecopexy were followed by prompt relief of constipation of long standing. The removal of innumerable small calculi throughout the entire gland substance, which are present is impossible. The future efforts must be directed toward relief of the pancreatitis rather than toward the removal of all the stones. Diabetes looms as ultimately inevitable as symptoms of an insatiable appetite and craving for sweets together with a greatly diminished dextrose tolerance are present. If attacks of pancreatitis continue unabated complete destruction of the pancreas by fibrosis is imminent and an existence maintained by diet and insulin will be all that the future can offer.

Congenital Anomalies of Ileocolic Region—Roberts believes that stasis in the intestine subjects the organism to the same potential dangers that attend obstructive lesions in other excretory systems of the body. Though wide variations in habit are commonly seen there must necessarily be a physiologic normal in which minimal intoxication occurs. Good function rests on a structural pattern that guarantees adequate muscle tone, ordered permeability and uninterrupted gradients of peristaltic motion. The anatomic deficit regularly associated with the intestinal invalid is not susceptible to appreciable alteration by operative attack. These patients belong to the

sphere of the internist and the psychiatrist. In a large proportion, however, much depends on the surgeon's interest in the developmental anomalies of the intestine, and the symptoms will be found due wholly or in part to mechanical factors susceptible to correction by the application of only sound surgical principles. When the toxic intestinal tide flows uninterruptedly until the compensation of vital organs, such as the liver, is lost, there arises a vicious chain that will not yield to attack on the focus in the intestine alone.

Venous Plexus of Esophagus—Kegaries demonstrated the submucous venous plexus of the esophagus in eight of sixteen cases by injection through the coronary vein of the stomach. The presence of a periesophageal plexus of veins was not demonstrated but rather a system of large venous trunks with the absence of cross anastomoses. Conclusive evidence of a channel of anastomosis between the portal and caval circulation at the cardio esophageal junction in the absence of portal obstruction has been demonstrated. Results of other workers concerning a connection between the spleen and the esophageal veins through the veins that accompany the vasa brevia have been confirmed. From this work, the author concludes that the venous plexus of the esophagus is a vulnerable structure and hemorrhage may occur in conditions other than portal hypertension, such as cardiac decompensation, diseases of the spleen and trauma or ulceration of the esophagus.

Etiology of Uterine Fibroids—In a previous paper Witherspoon and Butler offered evidence from 150 cases of fibroids in white women which they believe to be convincing in support of a hypothesis that ovarian follicle cyst formation with hyperestrin secretion, is an etiologic factor in fibromyomatous changes in the myometrium, provided the stimulation is prolonged sufficiently. They feel that their observations in 125 cases of fibroids in the Negro are additional evidence which confirm the original hypothesis. Their belief is that development of uterine fibroids in the white and Negro woman has the same source but that the Negro presents a greater frequency of occurrence of fibroids because chronic pelvic infection, resulting in ovarian damage and dysfunction, is more common than in the white woman, and this abnormal ovarian secretion the stimulation of which remains permanent, is prolonged sufficiently to be the igniting factor in the development of fibromyomas. The authors believe that ovarian follicle cyst formation in the white woman is the result of a general glandular disturbance, inherent in the organism as a whole. They doubt that this ovarian damage in the white woman need necessarily be permanent. Often it is not prolonged sufficiently to cause latent fibromyomatous myometrial changes even though the immediate hyperplastic endometrial changes are present since women who in early life exhibited hyperplasia

of the endometrium and, necessarily, ovarian follicle cysts later pass through the normal reproductive process, and the former glandular disturbance readjusts itself. As an explanation for the frequency of fibroids in the Negro woman, the authors offer the fact that ovarian follicle cyst formation, resulting from mechanical blocking due to a thickened capsule or disturbed blood supply from chronic pelvic inflammation, is a frequent observation, and when once initiated the hyperestrin secretion persists, since the damage is permanent, as long as ovarian tissue remains active. In the white woman, ovarian pelvic inflammation is a much less frequent observation, and often the ovarian follicle cyst formation is a result of general glandular upset and therefore is not permanent if a glandular readjustment can be obtained.

Vesicovaginal Fistula Technic for Its Correction—Ward reports the case of a married woman of 26 in whom a difficult forceps delivery resulted in a dead baby, a vesicovaginal fistula and the loss of the urethra. She had been operated on eight times in four years all operations ending in failures. In November 1932 the author operated as follows: An incision was made on the anterior vaginal wall above the fistula outlining a quadrangular flap 25 cc wide and 3 cc long. This flap was dissected from the vaginal wall up to the fistula leaving it attached with the upper margins slanting obliquely to the superior border of the vesical defect. The flap was formed into a tube by suturing the margins together after the technic suggested by Farrar. A soft rubber catheter was passed through this tube and into the bladder through the fistula. The site of the original urethra was dissected out so as to form a deep U shaped groove and the newly constructed tube was laid in this groove and its end with the catheter was brought out of the external meatus, which had been previously denuded of mucosa and sutured to it. The margins of the groove were brought together over the urethral tube and sutured with interrupted sutures. A Kelly mattress stitch of linen was placed at the neck of the bladder for control and the edges of the vaginal denudation were united with interrupted sutures. The wound healed by primary union with a perfect restoration of the urethral canal and closure of the fistula. The patient had some control of the bladder, but when on her feet the control was insufficient. Slight pressure on the urethra completely stopped the flow of urine and a satisfactory control was obtained by the use of a Thomas-Hodge pessary inserted in the reverse position. The exact amount of necessary pressure on the urethra was easily obtained by softening the pessary in boiling water and bending the bulbous end to the required angle. The patient has been perfectly dry and comfortable with the pessary ever since and she removes it for cleansing and replaces it herself whenever necessary.

Epiphyseal Separation of Long Bones—Elson and Ferguson analyze 110 cases of epiphyseal separations and make relative comparisons between the incidence of these injuries and fractures in the region of the joints in the growing age. Of the cases followed, 85.3 per cent obtained good anatomic and functional results. The results were fair or poor in 13.3 per cent the majority of these being in epiphyseal injuries of the lower humerus. Three cases of premature ossification resulted in excellent function but have been classed with the poor results because of the slight anatomic deformity. From the results obtained in the treatment of these epiphyseal injuries the authors draw some conclusions which may be useful in the future management of such cases. 1 Perfect reposition of the displaced epiphysis does not necessarily insure subsequent normal growth. 2 In most instances in which a single epiphysis forms the joint surface, partial reposition of the epiphysis was followed by normal subsequent growth (from two to eight years). This statement is particularly true of the lower radial epiphysis. Especially in the younger age groups nature seems able to compensate for considerable displacement. 3 Perfect reposition is most desirable in those areas in which several ossification centers are involved in the formation of the entire epiphysis e.g. lower humeral epiphysis. Displacement of these epiphyses and subsequent abnormal overgrowth may give marked impairment of motion in such a complicated joint. 4 Injuries in the region of the joints during the age of growth even in the absence of roentgen evidence, should be considered possible epiphyseal separations without displacement. Treatment

should be carried out with this possibility in mind. The prognosis of peripheral injuries should be guarded because of the danger of premature ossification and because the extent of the injury cannot always be determined at the time of injury.

*Cystocele Modification of the Neel Rawls Muscle Overlapping Technique H N Shaw Los Angeles—p 55

Cystocele—The modification of the Neel-Rawls technic used by Shaw, which was first described by Bissell, consists in denuding the mucosa from the muscle on one side only. The raw surface is drawn under the opposite flap by mattress sutures, and the combined flap of mucosa and muscle sutured to the cut edge of mucosa with a lock stitch. Overlapping the subvesical muscle for the cure of cystocele gives an excellent anatomic result, with relief of symptoms in a high proportion of cases. Denudation of mucosa from only one flap has two advantages over the Neel Rawls technic: (1) There is less interference with the blood supply of the tissue and (2) the time required for the operation is considerably less. In cases of prolapse, when childbirth or marital relations need not be considered, the author prefers vaginal hysterectomy to the interposition operation. He has operated in 134 cases of cystocele, using this modification and obtaining an excellent anatomic result, with relief of bladder symptoms in 125. In two cases, one diabetic, there was complete failure; in another vesicovaginal fistula developed; three patients died and three developed enterocoele.

Bronchoscopy in Obscure Pulmonary Conditions—Gordon states that the bronchoscopic examination of obscure pulmonary conditions is applicable to all ages is done without anesthesia affords the opportunity for removal of pus and secretion in the bronchial tree gives the opportunity for the direct inspection of the trachea and large bronchi enables one to secure uncontaminated specimens for bacteriologic study and permits the introduction of iodized oil in known amounts in either or both bronchi as indicated. A bronchoscope is introduced in the usual manner. All secretion is removed by suction. A small amount of anesthesia is applied to the tracheal bronchial mucosa. Then specimens for bacteriologic study are taken. Next a small cannula similar to the suction cannula is passed through the bronchoscope and the oil is injected first into the left bronchus if both are to be injected and then into the right. In children the quantity of oil injected must be graduated in accordance with age. The position of the oil cannula should be well above the division to the upper lobes and the oil should be about body temperature to make it flow more easily. The position of the patient on the table is important. The head and shoulders should be about 10 degrees lower than the horizontal plane and turned to the side to be injected. This permits the upper lobes to receive a sufficient amount of oil to give a good shadow. When the full amount of oil has been injected the table is slowly raised to about 15 degrees above the horizontal plane. The patient is then turned on his back. The bronchoscope is removed the patient is cautioned not to cough violently and the roentgenograms are taken.

Kaposi's Varicelliform Eruption—Brown says that no case of Kaposi's varicelliform eruption has been reported in the American literature. He gives the salient features in the cases reported first by Kaposi and later by Juliusberg, Galewsky and Rasch. The age incidence is that of infancy. In the case of Rasch and in that of the author the ages were 4 and 9 months, respectively. The condition seems to be a rare complication of infantile eczema. Almost all the cases recorded have presented eczema for some weeks prior to the onset of this unique eruption. The onset is sudden. There is elevation of temperature and pulse for at least twenty-four hours before the eruption appears. The eruption develops with great rapidity; a large crop may appear overnight and is most profuse on the face and head. There is high fever for from one to two weeks, with temperatures ranging from 102 to 104 F, then the temperature falls by lysis. The pulse shows a corresponding rise in rate from 130 to 150. There was no marked prostration in the author's patient. The clinical features of the eruption are described as varicelliform, vacciform or varioliform. Kaposi states very definitely that the lesions are like varicella but that they undoubtedly do not belong to this class. Rasch also described the eruption in his case as being like varicella but judging from the illustration the eruption appears also like variola. At no time in the course of the author's case did the eruption resemble varicella. No clear vesicles were present. The lesions were opalescent from the start and became rapidly pustular and varioliform in character. The main part of the eruption seems to develop over the previously eczematized skin but discrete lesions may appear elsewhere. Complete resolution takes place in the majority of cases, though Kaposi and Juliusberg each record a death. In addition to the eruption, Kaposi and others mention the presence of diffuse edema of the skin. This was present in a marked degree in the case here reported by the author. Some degree of pitting, such as is seen in variola, seems to be a feature in Kaposi's disease.

Kaposi's Varicelliform Eruption in an Adult—McLachlan reports a case of Kaposi's varicelliform eruption in a young woman. The clinical evidences presented by this patient were almost a reproduction of the case reported by Brown. Apart from the pustules being even more strikingly varioliform in the case of the child, the appearances were alike. This disorder does not appear to have been previously recorded in an adult, and its appearance in adult life in this case seems to be the only unusual feature. The preexisting eczematous state, the sudden onset and rapid course of a varioliform eruption, accompanied by acute edema and the subsequent scarring in the affected sites strongly support the diagnosis of Kaposi's varicelliform dermatitis. From the clinical appearances presented however, the term varioliform would seem to be more applicable to this uncommon ailment.

Ketogenic Diet in Treatment of Infections of Urinary Tract—Robb employed the ketogenic diet in sixteen cases of infection of the urinary tract. The diet had the effect of increasing the hydrogen ion concentration of the urine in all cases except one. The effect on the urinary pH was characterized by a rapid initial fall and a maintained low general level lasting till the end of the third week when there was a tendency

for the p_n to become irregular and to stand at a slightly higher level. Acetone bodies were produced in the urine in all cases but varied greatly in amount in individual cases. Acetone appeared in greatest amount during the first five days after the p_n had fallen and by the end of three weeks had become very much diminished. Five patients were cured completely by treatment with the ketogenic diet. The urinary figure was maintained about p_n 54 and acetone bodies were produced in satisfactory quantity. Four patients were cured following the addition of ammonium nitrate to the treatment two following the addition of methenamine and five were improved but the urines were not sterile. Of these, three left the hospital before treatment was completed, one was suffering from a subacute condition which interfered with metabolism and one failed completely to take the diet. Treatment with the ketogenic diet improved the symptoms and the characters of the urine rapidly. No symptoms were caused by the hyperacid urine. It was found desirable to increase the diet by stages according to the ketogenic-antiketogenic ratio, in order to avoid nausea and vomiting. Only one patient had any gastric upset. Two of the patients were nursing mothers. The milk was found to be of normal composition, and no gastro-intestinal symptoms were shown by the babies. Every patient was in excellent health on discharge from the hospital.

Chronic Nephrosis—Matthew and Cameron attempt to separate nephrosis from all other forms of nephritis and indicate that a definite diagnosis depends on the congo red test. Congo red is eliminated in the urine only in the small group of cases regarded as nephrosis. If nephrosis is an entity, there is still doubt as to its etiology and also as to the cause of various symptoms and signs present. The authors are of the opinion that certain changes in the kidney itself are primarily responsible for nephrosis and that the site of the lesion is the glomeruli and not the tubular epithelium. The permeability of the glomerular membrane (including Bowman's capsule and capillary wall) is increased and, in consequence, substances of larger molecular size than usual escape from the blood. With a damaged membrane showing increased permeability, serum albumin of molecular weight 67,500 will pass and appear in the urine while serum globulin which has larger molecules of about 103,000 cannot escape. As a result, in nephrosis excessive quantities of albumin are found in the urine but no globulin, and correspondingly there is a serious fall in plasma albumin but no change in plasma globulin. In addition, albumin exerts an osmotic tension approximately six times that of globulin. The decreased protein in the blood is due to the loss of albumin, and so there is a great fall in its osmotic power. The blood is unable to hold its normal amount of fluid, and water passes from it to the tissue cells in increasing amount, so that progressive edema occurs. It is believed that in the attempt to restore the osmotic tension hypercholesterolemia ensues. Thus the authors regard altered glomerular permeability as the primary renal change in nephrosis and make various suggestions to account for the change. They believe that the sequence of events ending in nephrosis would therefore be (1) an infective condition (2) degeneration of the glomerular membrane ending in increased permeability, which allows the escape of serum albumin but not of serum globulin or fibrinogen (3) marked fall in plasma albumin no fall in plasma globulin (4) fall in osmotic tension of the plasma, (5) edema that tends to increase and become very marked and (6) hypercholesterolemia. They

suggest that nephrosis is merely syphilis of the kidney. In their two patients only one had had syphilis, and in addition, other patients having albuminuria were undoubtedly syphilitic, yet none had the typical nephrosis congo red response. Nephrosis undoubtedly occurs in nonsyphilitic subjects and although albuminuria occurs often in syphilis, this does not constitute nephrosis. Cases in the literature bear out this argument.

Pregnancy and Rheumatic Heart Disease—Gilchrist and Murray-Lyon analyzed 109 cases of fatal cardiac rheumatism in an endeavor to discover the effect of repeated pregnancies on the course of the disease. A comparison has been made between men, nulliparous women and parous women regarding their average age at death, mode of dying, duration of the cardiac disease and the rate of progression to the fatal termination. All the patients suffered from mitral stenosis either alone or in association with other valvular lesions. No significant difference was found in the duration of the disease in nulliparous and parous women. The course of the disease appeared to be shorter in the male patients. Auricular fibrillation is not necessarily an indication that an additional burden has been placed on the heart during the child-bearing period. Its incidence is largely determined by the length of survival from the time of the first involvement of the heart. Congestive heart failure was the mode of death in 92 per cent of the whole group. The fact that these parous women dying from congestive heart failure had families averaging 4.5 children each would support the contention that repeated child bearing accelerated their earlier death. Cerebral embolism accounted for all the remaining deaths with two exceptions. Parous women dying from this cause lived an average of twelve years longer than those who died from congestive heart failure. In spite of their longer life their families averaged only 1.7 children. It would appear that by escaping the burdens of a large family they guard themselves against the risk of congestive heart failure until the age of about 38 years, only to die from embolism twelve years later. This would appear to be about the maximal span of life for the individual dying from rheumatic heart disease. While pregnancy should be avoided in the severer grades of rheumatic heart disease, the authors conclude that one or two children may be borne without detriment by the majority of women suffering from cardiac complications. Repeated pregnancies however, tend to shorten the span of life in women suffering from rheumatic heart disease and ultimately increase the risk of death from congestive heart failure.

Associated Paralysis of the Vocal Cord—Burger states that there can be few laryngologists and not a single neurologist who without consulting books, can tell exactly the difference between the syndromes of Jackson Collet, Vernet and Schmidt. Even those who write about them often mix them up. These names are impractical, are incorrect and lead to confusion. When, by a progressive process at the cranial base, today the vagus tomorrow the accessory later on maybe the hypoglossus, and eventually the glossopharyngeal nerves are attacked it is pointless to speak of the transition of the syndrome of Avellis into that of Schmidt, into that of Jackson, or into that of Collet. And as each of these can be accompanied by disorders of the sympathetic facial and auditory nerves and, for instance, of the pyramidal tract the list remains hopelessly incomplete. Such progress may be observed with degenerative diseases in the medulla oblongata as well as with syphilitic and neoplastic processes at the cranial base. Similarly with disturbances on the side the skull. Lemaitre who in a progressive process in the cervical glands watched the symptoms of paralysis successively traverse new nerve territories points out the artificiality of this classification into syndromes. Neurologists are in daily

contact with associated paralyses of cranial nerves, but they do not fetter their minds by trying to fit every combination into a little compartment with a name of its own. The only serviceable classification is that according to the typographic situation of the maladies: syndrome of the bulbar nerves, syndrome of the jugular foramen syndrome of the parapharyngeal space and vocal cord-diaphragm syndrome.

Medullo-Epithelioma (Bailey and Cushing)—Greenfield reports two cases of medullo-epithelioma of the cerebrospinal system. One was a supratentorial growth subjected to partial operative removal less than two years after the onset of symptoms, showing evidence of regrowth three years after operation and then arrested for two and one-half years by roentgen therapy. The other originated in the sacral canal, where it continued to grow without greatly enlarging the canal for about six years. It then spread to the subarachnoid space, where it rapidly produced numerous secondary growths over the spinal cord and brain. Such evidence as to rate of growth and relative malignant condition of the medullo-epitheliomas as these two cases afford halts between the opinions expressed by Bailey and Cushing and those by Roussy and Oberling. While giving no support to the contention of the former that medullo-epitheliomas are more malignant than medulloblastomas it does not favor the view of the latter that medullo-epitheliomas (a form of their neuro-epitheliomas) are in general tumors of slight malignant manifestation. Nor does the second case support their contention that when a neuro-epithelioma takes on the characters of a frankly malignant growth it evolves toward the type of neurospongionoma (medulloblastoma) as there was little change in the structure of the tumor from that seen in the old standing sacral growth to that of the recent rapidly growing cerebellar metastases. On the whole however these cases support the view of the French authors that medullo-epitheliomas are dysembryomas (dysembryomes evolutifs) whereas medulloblastomas are true cancers of the nervous tissue. This view is in accordance with that expressed by Davie who while producing no fresh evidence as to rate of growth discussed the position of medullo-epitheliomas among tumors of the nervous system. At the same time his suggestion that medullo-epitheliomas may turn out to be relatively benign and slow growing is not fully substantiated. All that the present two cases show is that the rate of growth of this form of tumor is subject to various influences, only some of which appear to be explicable on physical grounds. They resemble the more malignant growths in being radiosensitive and in the power of rapid growth under favorable conditions but they are probably more susceptible to restraining influences of various kinds than the anaplastic growths of nervous tissue.

Pneumococcus Hemolysin—The investigations of Cowan indicate that hemolysin is found in the fluid part of young broth cultures of the pneumococcus. The maximal titer occurs immediately after the phase of logarithmic growth. The relation of the curve of the titer of hemolysin to the curves of the total and viable counts indicates that hemolysin is given off into the surrounding medium by the pneumococcus and that its presence there is not essentially the result of autolysis. The fall in titer of hemolysin in older cultures is due in part to its inactivation by oxidation. Its activity can be restored

by reduction with sodium hydrosulphite. Hemolysin deteriorates during storage if oxidation is permitted, it can be kept satisfactorily in sealed ampules if air is excluded. Hemolysin is not type specific and the capacity of a strain to produce hemolysin varies independently of virulence. Hemolysin filters readily, is rapidly destroyed at 55 C and is antigenic. Of twenty-eight strains examined only two failed to produce hemolysin. It is possible that individual pneumococci in any culture differ in their capacity to produce hemolysin. The addition of blood to the medium in which a strain is maintained in subculture assists the retention of its capacity to produce hemolysin. The erythrocytes of man are somewhat more sensitive to hemolysin than those of the rabbit or guinea-pig. Hemolysin is adsorbed almost immediately by erythrocytes and by pus, and is not usually demonstrable in inflammatory exudates.

Effect of Diet, Insulin and Thyroxine on Suprarenals—The experiments of Gohar indicate that the epinephrine content and the weight of the suprarenals are affected by variations in the diet. While a high protein diet has no marked effect a fat diet leads to a diminution of the absolute content of epinephrine and of the total weight of the glands. The relative amount of epinephrine per gram of gland is also slightly diminished. A carbohydrate diet also leads to a diminution of the absolute content of epinephrine, the weight of the suprarenals is strikingly diminished so that the relative amount of epinephrine per gram of gland is considerably increased. The repeated administration of insulin in subconvulsive doses leads to an increase in the weight of the suprarenals and of their epinephrine content. In convulsive doses, insulin leads to a depletion of the epinephrine store. This effect of insulin is produced through the nervous system as well as by peripheral action on the suprarenal bodies. The repeated injection of thyroxine also leads to an increase in weight and of epinephrine content of the suprarenal bodies.

Nephrosis in Malaria—Menon and Annamalai report a case of nephrosis in which the demonstration of malarial parasites in the spleen smear and of malarial pigment in sections of the spleen liver and other organs and the characteristic morphologic changes in the liver and spleen showed a massive infection with malaria. The degenerative change in the tubules of the kidney with but slight change in the glomeruli is in consonance with the view that a necrotizing type of nephrosis is the actual lesion in the kidney. The marked enlargement of

the kidney the presence of necrosis and the formation of casts all show that the change is not a mere fatty degeneration such as is encountered in anemias. The absence of proliferation or crescent formation in the glomerular tuft and Bowman's capsule is quite unlike the appearance encountered in the large white kidney of subacute glomerulonephritis. The demonstration of neutral fat and of double refracting fat is conclusive that the change is a degenerative type of nephropathy. Bell has pointed out that nephrosis is not a distinct entity but a form of glomerulonephritis in which the injury to the glomerular capillaries is of such a type that no reactive proliferation occurs but their permeability is affected, so that albumin is allowed to escape in large amounts. The presence of malurial pigment in the epithelial cells of the proximal convoluted tubules raises the possibility that this is the hypothetical toxin that is responsible for the nephrosis. The only possible explanation of its presence in this part of the tubule, in which resorptive functions are not great, is that the pigment is being excreted by the kidney and has caused severe degenerative changes during the process. The malurial infection is apparently of long standing. The fact that the patient was unconscious when brought to the hospital raises the question of uremia as a cause of death.

Cutaneous Reactions to Products of Hemolytic Streptococcus—McGibbon has found it possible to demonstrate a condition of hypersensitiveness to products of the hemolytic streptococcus during the course of scarlet fever. He used an extract representing the soluble intracellular products of the organism freed from all diffusible substances. About 90 per cent of seventy-four cases, including all the patients more than 7 years of age have shown a positive reaction by the fourth week. The author discusses the relationship of this allergic state to scarlatinal nephritis and arthritis and its possible importance in the development of the rheumatic state. A total of 160 persons not suffering from scarlet fever have also been skin-tested. In all cases age has an important influence on the results. Retests both in health and in a wide variety of diseases have produced no material change in the reaction. The latter appears to be inhibited in chronic cardiac disease and wasting conditions, but not in acute infections, unless these are of great severity. The results in erysipelas contrast sharply with those in scarlet fever. In erysipelas the reaction to the hemolytic streptococcus extract is positive in the first week and appears to remain so throughout the disease. In the absence of extreme illness, a negative reaction in an adult patient should therefore question the diagnosis of erysipelas.

*Transplantation of Suprarenal Glands in Addison's Disease F d Abreu—p 1478

Nature of Functional Disturbance in Cocaine Hallucinations K Zucker—p 1479

Transplantation of Suprarenals in Addison's Disease—Although the grafting of the suprarenals in d Abreu's case of Addison's disease eventually failed, owing to suppuration around the grafts, a definite though temporary improvement was caused by the transplantation. The patient was in an advanced stage of the disease and in an unsatisfactory condition for a

successful result. The only available suprarenals were those of a woman of 73 who was not an ideal subject and from a still born infant who was premature and poorly developed. Therefore the author feels that the amount of improvement noted in this case, in which conditions were unfavorable, and the results in the three cases reported previously by other authors warrant the further trial of this operation in cases of Addison's disease. Points in the actual technique of the operation which, from a consideration of this case and the available literature, seem to be worthy of attention are as follows: 1 The graft should be removed from the dead patient as soon after death and with as much care for asepsis as possible. Opportunities for using a suprarenal of a patient still alive must be so rare that the possibility should not, to the author's mind, be considered for general application. 2 From the behavior of grafts in general it is seen that grafts in strips are more likely to function than whole glands, as a functioning graft is that which is actually penetrated by the blood vessels of the host, such penetration rarely exceeding a depth of 2 mm. Preferably, on general grounds, the donor and recipient should be of the same blood group. 3 In view of the harmonious working of the testicles and the suprarenals and the success of such a graft as that reported by Hurst, the testicles seem to be the most favorable site. In ruling this, a site between the peritoneum and the muscles of the abdominal wall should be employed.

*Value of Sanoerysim in Therapeutic Pneumothorax J Cribbin—p 145

Memorandum on Asbestosis E R A Merewether—p 152

Value of Gold Therapy in Therapeutic Pneumothorax—Although Cribbin feels that the actual number of cases (nineteen) investigated is too small to warrant conclusions the investigation has a particular value in that it emphasizes the essential criterion from which an absolute evaluation of the therapeutic efficacy of a double thiosulphate of sodium and gold ("Sanoerysim") may be gained. The results offer convincing support in favor of combined pneumothorax and double thiosulphate of sodium and gold therapy. Recent experimental investigations that are of considerable importance to chemotherapeutic study have assigned to the reticulo endothelial system an important part in the mechanism of chemotherapeutic action. The action of double thiosulphate of sodium and gold on the reticulo endothelial system has not as yet been made the subject of special study. Schroder states that it does stimulate the reticulo endothelial system. Hughes and Shrivastava, Houghton and many others have demonstrated that definite changes in the blood elements following its administration may occur—in favorable cases associated with an increase of lymphocytes (reticulo endothelial cells) and in unfavorable cases with an increase of monocytes. Sabin shows that an increasing lymphocytosis occurs with a well maintained resistance (immunity). It is conceivable that the power of double thiosulphate of sodium and gold to cause an increase of lymphocytes is greater than is possible with other stimuli (tuberculin albumin horse serum), and that as a result the changes induced are more helpful and beneficial to the natural defenses of the body. A comparison of the death rates of patients treated with it and those not treated with it is of practical importance. Thus, Clarke found that 69 per cent (moderate and advanced groups combined) who were treated with it were alive, as contrasted with 46 per cent who did not have it. An immunologic response with subsequent increased resistance must be at least a partial explanation of the difference in the death rates.

*Influence of Intercurrent Infections on Evolution of Kala Azar P Giraud and R Poinso —p 81

Influence of Intercurrent Infections on Kala-Azar—Giraud and Poinso report eleven cases of kala-azar in which treatment with various antimony compounds failed to cause notable amelioration, but the appearance of febrile intercurrent infections (measles, pneumonia, bronchopneumonia and so on) resulted in marked improvement. In one case, resistant to antimony, febrile reactions followed each of ten injections of acetarsone. The size of the spleen decreased, the patient became fever free and the general condition was improved. In ten other cases, intercurrent infections had definitely unfavorable results and the patients died. The authors believe that under certain circumstances intercurrent infections can produce marked amelioration of the kala azar by means of the hyperpyrexia. This is especially true in those cases which are antimony resistant. Further studies are necessary to prove whether artificially produced hyperpyrexia is to be of value in antimony-resistant cases of kala azar.

*Blood Chlorides and Postoperative Toxic Syndrome H Chabanier and C Lobo Onell —p 251

Blood Chlorides and Postoperative Toxic Syndrome Chabanier and Lobo-Onell, although unwilling to admit that the usual decrease in blood chlorides is of no importance, believe that it does not constitute the primary factor in the toxic postoperative state. Their reasons are threefold. In some instances of postoperative toxemias the blood chlorides may be normal or higher than normal. Inversely it is not uncommon to observe lowering of the blood chlorides postoperatively without toxic symptoms. Finally the independence of the toxic state and blood chlorides are manifest in therapeutic rechloridation. The authors suggest that the common cause is the general anesthesia. A vicious cycle is set up which involves more vomiting, more appearance of chlorides in the tissues where the toxic substances (probably nitrogenous) are liberated and appear in the circulation with accentuation of the toxic syndrome, and more vomiting. They conclude that the primary factor in the toxic postoperative syndrome consists in the liberation into the circulation of toxic substances at the seat of the operation. This effect is soon reinforced by the appearance of insufficiently split nitrogenous substances liberated from the tissues.

Choice of Technic for Better Selection of Irradiations V Palumbo —p 336

Pathogenesis of Chronic Pancreatitis—Rossi believes that when pancreatitis is associated with ulcer and with cholecystitis, it does not represent a morbid succession of the latter but a distinct localization of the right abdominal syndrome. As causes of chronic pancreatitis in the literature the author found chronic intoxications, acute hematogenous diseases, specific chronic diseases (syphilis and tuberculosis) and primary inflammation of the pancreas. He acknowledges the importance of these factors but maintains that most chronic pancreatitides are secondary to diseases of nearby abdominal organs. In a simple right abdominal syndrome or in a right abdominal syndrome associated with cholecystitis or ulcer, the inevitable change in the internal and general function of the pancreas is manifested by the lipolytic power of the serum and by an increase of the glycemic curve during fasting. Thus the pancreatitis does not depend on the ulcer or cholecystitis

but on the lesions of the right abdominal syndrome which in turn may have produced the ulcer and the cholecystitis. The infection may arrive at the pancreas by way of the lymphatic system, the blood stream, by direct extension or through the omentum. The lymphatic route, however, seems the most logical way of explaining a chronic infection transferred from the appendix to the pancreas.

Diaphragmatic Hernia and Its Treatment J Lazarraga —p 158

New Interpretations of Glycemic Curves—Jimenez Garcia states that, in order to obtain the best diagnostic value of the curves of the provoked hyperglycemia test in pancreatic insufficiency, prediabetic conditions and diabetes, it is advisable to administer to the patient a restricted diet containing from 100 to 120 Gm of carbohydrates daily for four days immediately before the performance of the test. The exact amount of dextrose to be given to the patient is 50 Gm dissolved in 250 cc of water. The dose of 20 or 25 Gm of dextrose is too weak for diagnosis in doubtful cases. Doses of 100 Gm of dextrose are unnecessary, since the hyperglycemia figures are the same after the administration of 50 Gm as after the administration of 100 Gm of dextrose. Fixed doses of dextrose are more useful and are best compared with one another than doses calculated per kilogram of body weight. The long glycemic curves with five determinations of glycemia during three hours are useful, since they permit the observations of all the changes of glycemia during the test. Periods of one or two hours are not sufficient to determine all the changes of the glycemia during the test, since in a large percentage of the cases the glycemic curves have not reached their maximal value during the first hour and have not shown the phase of reactional capacity of the pancreas that takes place before the second hour. More than three hours is unnecessary because in all cases after three hours the descent of the glycemia to the initial figures has begun. According to the author's method, curves should be considered normal if they are within the maximal and minimal figures given by the author in graphic instead of fixed figures, as other authors have advised, since some of these curves may either begin or end in 11 Gm and yet be as normal as those having lower values. To obtain the maximal diagnostic information of a glycemic curve, one must observe the figures given by the initial glycemia, ascending and reactional phases of hyperglycemia and the greatest height of the glycemia with the patient prepared as previously indicated. With all the preceding factors one has an exact idea of the importance of the glycemic curve in frank cases and the risk of false diagnostic interpretations of the curves decreases considerably in doubtful cases. The highest figure of glycemia in relation to that of the initial glycemia marks the degree of insufficiency of the glyceregulatory complex having diagnostic value. The reactional change of glycemia that denotes the functional capacity of the pancreas is of great prognostic value.

Treatment of Pollen Allergy—Hansen shows that specific desensitization is a highly effective therapy which if the correct doses are given is successful in more than 75 per cent of cases. Failures occur in less than 10 per cent and he thinks that even this number may be reduced if all factors are given careful consideration.

Viper Bites—Frey relates observations on thirteen viper bites. The measures that had been taken either by lay persons or by a physician before arrival at the clinic were tying off of the injured extremity in six cases, sucking of the wound in three cases, application of poultices in three cases, excision of

the wound in two cases, cauterization in one case, injections of potassium permanganate around the wound in one case, and injection of serum in one case. Three patients had received no aid whatever before arrival at the clinic. The author maintains that the efficacy of sucking the wound is largely illusory and of just as little avail as it would be to try to weaken a too strong morphine injection by sucking the injection puncture. He thinks that there might be a result if immediately following the bite two incisions could be made and the sucking could be done with a suction cup, but incision by a lay person is certainly dangerous and suction with the lips involves the danger of facial infection. The tying off of the extremity he considers likewise of little help not only because he considers the underlying theory as not well founded but also because he observed in some of the patients in whom the member had been tied off that the general reactions were unusually severe. To the infiltration of the tissues with chemical substances he likewise ascribes little value. In the clinic the treatment generally consisted in immobilizing bandages, serum injections and general therapeutic measures. In three cases stasis was employed, incision was done in two cases and cauterization in one. Thus there was an opportunity to estimate the efficacy of several methods and the author concludes that immobilizing wet dressings, general measures and especially serotherapy constitute the best treatment. Serotherapy is employed in the form of intramuscular injection of 10 cc of serum near the bite. If threatening general symptoms have developed already a dose of 40 cc should be injected intravenously, provided the patient does not have a hypersensitivity to horse serum. The shutting off of the poison focus by means of injections of the patient's own blood around the focus was tried in three cases in which the bites were on the fingers or toes. A definite evaluation of this autohemotherapy is as yet difficult but it was observed that one of these cases took an unusually favorable course.

Gastric Neurosis.—Doerfler combines all disorders under the term gastric neurosis in which pain in the gastric region is complained of and in which anatomic changes can be excluded but he admits that the physician is never sure even in the most exact roentgenologic examination, whether a gastric or duodenal ulcer is present or whether the disorders are of neurotic origin. This is the more understandable as even the gastric ulcer is now considered a phase of a vagoneurotic syndrome. In practice it is essential to make a differentiation between a functional and an anatomic disorder, for in gastric neuroses the result of the treatment is largely dependent on the suggestive power of the physician because in disturbances that have developed by way of the central nervous system that is by autosuggestion only a higher suggestive power can be effective. The author considers a constitutional inferiority manifested in the relations of the central nervous system to the sympathetic nervous system the underlying cause of gastric neurosis. Persons who are affected in that manner may react to irritating influences in the mode of living, overexertion, anxiety, vexations, unsatisfied ambitions and nervous toxins, such as nicotine and alcohol with painful hyperfunction or hypofunction of one or several organs that have a sympathetic innervation. If a patient complains of prolonged gastric disturbances the physician should first try to get a picture of the personality of the patient. A patient with cancer or ulcer generally describes his symptoms more quietly and complains of not being able to tolerate certain heavy

foods while the patient with neurosis occasionally admits that a particularly heavy meal was well tolerated. It is characteristic for the neurotic patient that his pains frequently disappear when his interests are directed into other channels, particularly when he enjoys himself or is well entertained. This is not the case in patients with cancer or ulcer. If the physician is convinced of the nervous origin of the gastric disorder he should not tell the patient outright that everything is due to nervousness. He should be told of the spastic conditions that exist. The patient should not be put on a restricted diet but should be encouraged to eat heartily. If the patient fears a heavy meal, he may be encouraged by simultaneous medicinal treatment.

Auto-Infection in Carriers of Diphtheria Bacilli.—Lausecker observed two diphtheria carriers who transferred the bacilli to small skin defects: the first child to a smallpox (vaccination) pustule, the second to rhagades at the angle of the mouth. As a result, ulcerations developed. In the first case local application of antitoxic serum effected a cure within a few days. The child's general condition was only slightly impaired. The second child was given intramuscular injections of antitoxin. During the severest stage the child had a temperature of 39 C (102.2 F), but after the serum injection the fever decreased and on the second day it had entirely disappeared. The Schick test was positive in both children and both harbored diphtheria bacilli in the nose. The bacilli detected in the skin lesions were definitely identified as diphtheria bacilli for they failed to ferment saccharose and they were identified also in the animal experiment.

Spontaneous Fractures of Neck of Femur Following Roentgen Irradiation.—Kropp relates the history of a woman, aged 67, who three years previously had undergone Wertheim's radical operation because of carcinoma of the uterine cervix. This operation had been followed by three radium and six roentgen irradiations. In the following years the patient was examined regularly but pathologic conditions were absent and she felt well. When she came for a new examination at the end of 1933 she related that three months previously, when walking down hill she had suddenly felt a severe jolt and pain in the left thigh. A physician, consulted at the time, could detect nothing. When she came for a regular examination, a roentgenogram showed a median fracture of the neck of the left femur. The author emphasizes that in determining the pathogenesis of such fractures one should not overlook that spontaneous fractures occur in aged persons and that the neck of the femur is the site of predilection for such fractures. Even slight traumas may produce such fractures. However, in the case reported not the slightest trauma could be found. Changes due to aging must be taken into account, although they were not evident in the roentgenogram. The author emphasizes that during the irradiations only the heads of the femurs lay within the region of the rays but he admits that in other cases with different size relations the rays may strike the necks of the femurs. At any rate he thinks that in corresponding complaints of patients who have been treated with roentgen rays, spontaneous fractures should be looked for.

New Method for Treatment of Multiple Sclerosis.—Horn, in treating patients having multiple sclerosis, noted that the injection of silver preparations effected temporary improvements. In order to make the favorable effect of the silver therapy more lasting he decided to combine the silver treatment with injections that would reduce the silver. In the evening and in the morning an hour before the first injection

the patient is given a teaspoonful of sodium bicarbonate. The first injection, consisting of 5 cc of an electrolyzed colloidal silver preparation, is given at 9 o'clock, and until this time the patient should have no food. At 11 o'clock 10 cc of a 33 per cent solution of dextrose is injected. On the following morning, likewise on an empty stomach, the patient is given an intravenous injection of 10 cc of water, in which 0.5 Gm of sodium thiosulphate has been dissolved. After an interval of from four to seven days, the same procedure is repeated. In the further course of the treatment the doses of the electrolyzed colloidal silver and of the dextrose solution are gradually increased, while the dose of sodium thiosulphate remains the same. The author reached the maximum of 12 cc of electrolyzed colloidal silver and 20 cc of dextrose solution at the eighth injection. He advises from eight to twelve repetitions of the combination of the three injections. Only one of the eight cases treated by him was an incipient one, in all the others the symptoms had been present for a number of years. In the incipient case, complete remission was obtained and the other patients showed various degrees of improvement. The longer the disorder had existed, the slighter was the improvement. At any rate, the treatment brought about remissions in cases that had been refractory to all other treatments.

Calcium Therapy of Rheumatic Disorders—Zenoff resorted to calcium therapy to effect desensitization. He controlled the curative process by determining the sedimentation speed of the erythrocytes and found that particularly in the acute forms of rheumatism the accelerated sedimentation was gradually normalized under the influence of the calcium therapy. Fifty-five patients with acute articular rheumatism were given daily injections of 10 cc of calcium gluconate (in all, from fifteen to twenty-five injections). In addition to this they were given sodium salicylate by mouth, on the first few days 12 Gm and later less. This treatment counteracted the fever in from ten to twenty-six days. Injections of calcium gluconate were used as the only therapeutic procedure in twenty-three cases of acute and twenty-eight of chronic rheumatism. In these cases the first few injections of calcium gluconate frequently caused an acute exacerbation, but finally the calcium injections effected a complete remission. Aside from counteracting the pain and from restoring the mobility of the joints, the treatment has the advantage that cardiac impairments develop only in extremely rare cases. When the treatment was conducted in the proper manner (control of sedimentation of erythrocytes), relapses were never observed within a year. The author recommends the treatment for further trials.

Poliomyelitis During Preparalytic State—Specific Treatment—Siegl shows that, since the specific serotherapy of poliomyelitis is fully effective only if it is given during the preparalytic stage, it is important that the disorder should be diagnosed during this stage. After a symptomless incubation period of from seven to ten days, the prodromal symptoms appear and consist usually of a slight rise of temperature, increase in vomiting, headaches and pharyngitis. In the majority of cases there exists constipation, diarrhea is comparatively rare. These symptoms, which vary in severity, persist for one or two days. Then there frequently follows a symptomless period for several days, which in turn is followed by the preparalytic stage, but even during this stage the symptomatology is at first not clear. The symptoms of the upper respiratory tract and the gastro-intestinal symptoms may lead to an incorrect diagnosis, for fever and blood picture are still lacking the characteristic aspect of poliomyelitis. During an epidemic the development in two periods may draw attention to the possibility of a poliomyelitis. Otherwise a definite diagnosis can be made when the spinal meningeal symptoms, the rigidity of the neck and of the spinal column, the generalized or localized hyperesthesias and the atactic tremors appear. The pains are localized particularly in the back and in the lower extremities. There may be a pressure sensitivity of certain nerve trunks and a feeling of weakness in the extremities. Hypersensitivity of the skin in the form of profuse perspiration, temporary redness and occasionally exanthems may also appear. The preparalytic stage the symptoms of which vary in severity and may even be lacking entirely, as a rule lasts from two to five days and is followed by the development of the paralytic symp-

toms. The author advises lumbar puncture in all cases in which poliomyelitis is suspected for the cerebrospinal fluid shows inflammatory changes during the initial stages. The pressure is generally increased. The fluid is either clear or slightly clouded as with dust, the latter being the result of an increase in cells, particularly lymphocytes. The protein reactions are usually positive. The sugar values are normal or increased but never reduced, the latter factor may be helpful in the differentiation from other forms of meningitis. In discussing the serotherapy, the author maintains that treatment with convalescent serum, especially mixed serums, is the best. He considers intraspinal administration of from 10 to 20 cc the most effective method but advises that simultaneously from 20 to 50 cc should be given intramuscularly. If the intraspinal administration is not feasible, from 20 to 60 cc should be injected into the muscle. In the event that convalescent serum is not available, horse serum may be given. Shottmüller has recommended blood transfusions, persons who have had poliomyelitis serving as donors.

 *Isolated Actinomycosis of Kidney. H. Schneider—p. 105
 Double Kidney and Hypernephroma. E. Simon—p. 111

Renal Glycosuria in Patient with One Kidney—Since reports on unilateral renal glycosuria are rare, Strauss describes a new case, which differs from the others in that the patient had only one kidney, the other one having been removed several years ago. The glycosuria persisted for several days but later on even a dextrose tolerance test did not produce glycosuria. The blood sugar was low at first and slowly increased to normal values. During the dextrose tolerance test the blood sugar curve was abnormal (low peak of curve and rapid descent below the starting point). The hyperglycemic stage was not much below the blood sugar value at which formerly sugar elimination had taken place. As the cause of this renal glycosuria a pancreatic diabetes could be excluded with certainty, but an involvement of the central organ of the sugar regulation could not be completely excluded. The author calls attention to the observation that an injury of the anterior portions of the dorsal vagus nucleus may be followed by a reduction in the blood sugar, but he also points to the possibility of a modification of the metabolic processes by an acute infection. He admits that the occurrence of hypoglycemia in the course of acute infections could perhaps be explained by hyperinsulinism, but this does not explain the glycosuria. The presence of only one kidney as cause of the pathologic sugar metabolism can be rejected on the basis of blood sugar tests before and after nephrectomy on patients without metabolic disturbances. In the absence of tangible causes of the glycosuria in case of a low blood sugar content the author classifies the case with cases of renal diabetes. He contrasts with this case of glycosuria with low blood sugar postoperative cases of aglycosuria with increased and high blood sugar in persons without metabolic disturbances and in diabetic patients. Eliminatory disturbances of the kidneys, due to failure of the glomerular filtration are largely responsible for the partial or total sugar blockage. In most of these renal disturbances the increase in the blood sugar content is accompanied by an increase in the rest nitrogen. The retention uremia can be treated by repeated venesections and by continued intravenous drop infusions with isotonic solutions of sodium chloride, and the disorders in the sugar metabolism can be influenced by administration of insulin and dextrose. The author thinks that the combination of hyperglycemia and of an increase in the rest nitrogen may cause postoperative fatalities particularly in urologic surgery. To avoid such fatalities he advises the determination of the blood sugar content and of the rest nitrogen before and after surgical interventions.

Isolated Actinomycosis of Kidney—Schneider points out that some textbooks of urology speak of primary actinomycosis of the kidney and mean an isolated actinomycosis of one kidney when all other organs are free from the disorder and a port of entry of Actinomyces cannot be found. Strictly speaking primary actinomycosis of the kidney is impossible for only a

secondary involvement from a primary focus by way of the blood stream is possible. For this reason the author thinks that the designation primary actinomycosis of the kidney should be avoided and that the term isolated actinomycosis of the kidney should be used. He reports a case. The necropsy revealed that all other organs were free from actinomycosis and that a port of entry could not be found. On the basis of the anatomic picture it must be assumed that the fungus reached the kidney by way of the blood stream. The author considers it important to know that Actinomyces may develop in the renal tissues, unnoticed for a long time and without perforation into the renal pelvis. But even if such perforation does take place, it appears that the renal pelvis, the ureter and the bladder may remain free from actinomycosis. It is apparently possible for the kidney to eliminate the fungus and yet remain free from organic impairment. Actinomycosis seems to favor the development of calculi in the renal calices. A trauma or, as in the related case, a surgical intervention may lead to a sudden exacerbation of a formerly hidden actinomycosis of the kidney.

Serum Treatment of Peritonitis—According to Gundel and Sussbrich bacteriologic studies of cases of acute appendicitis in the Heidelberg clinic demonstrated the importance of the enterococci and the closely related nonhemolytic strains of streptococci. These organisms recede into the background with the development of an abscess or of postappendical peritonitis. Here the important part is played by *Bacillus coli* and gas gangrene bacilli. The pathologic effect of the gas bacilli is uncertain and probably not of great importance. The other bacteria found in the pus are secondary invaders although they may aggravate the morbid process. Their clinical experience controlled by bacteriologic studies indicates that a peritonitis serum to be of value must have for its object the development of antibodies against at least three organisms: *B. coli*, gas gangrene bacilli and enterococci. The bacterial flora in peritonitis due to other perforative causes, such as perforation of a gastric ulcer or of an empyema of the gallbladder, is essentially the same with perhaps quantitative differences. *B. coli* is likely to be present in any perforative peritonitis. The authors treated 170 cases of peritonitis, with a mortality of 10.5 per cent. The technic of administration is as follows. On the termination of the operation, 20 cc of the serum may be introduced into the peritoneal cavity through the rubber tube drain, or it may be administered intravenously, from 20 to 40 cc in 1,000 cc of a 5 per cent solution of dextrose. For prophylactic treatment, from 20 to 40 cc is introduced intravenously in 500 or 1,000 cc of a 5 per cent solution of dextrose. In abscess or peritonitis this dose is repeated on subsequent days. In the Heidelberg clinic, peritonitis serum is used prophylactically in all operations on the gastro-intestinal tract, particularly resections.

Zentralblatt für Gynäkologie, Leipzig

- New Clamp for Ligation and Division of Umbilical Cord. M. C. Boon von Ochssee — p. 391

Disturbances Resembling Eclampsia—Fikentscher points out that eclampsia involves primarily the kidneys, liver and brain and that owing to the more severe involvement of the

one or the other of these organs, a great variety of clinical pictures is possible, in which the differential diagnosis may be difficult. The renal symptoms predominate in most cases of eclampsia, and a differentiation from renal diseases, particularly from those that are accompanied by uremia and convulsions, may raise difficulties. In eclampsia with predominating hepatic symptoms, a differentiation from acute yellow atrophy of the liver may be difficult. However, the greatest differential diagnostic difficulties are encountered if the cerebral symptoms predominate, for organic or functional disorders of the brain leading to convulsions may be hard to distinguish from eclamptic convulsions. Epilepsy is the most frequent of these cerebral disturbances, but the author shows that the rarer cerebral disorders may occur during pregnancy and may be confused with eclampsia. The two cases reported, (1) cerebral tumor during pregnancy and (2) metencephalic attacks during pregnancy and delivery, belong to the rare cerebral complications of the process of gestation. The clinical aspects of both cases were such that a confusion with eclampsia or its preliminary symptoms was likely and on the basis of these observations the author emphasizes that obstetricians should not overlook the fact that during gestation there may develop eclampsia-like conditions the causes of which do not lie in pregnancy. The reported cases demonstrate the close relations between nervous functions and gestation processes, and how much the two influence each other. The history of the patient with the cerebral tumor reveals that lingering disease processes may suddenly become manifest during pregnancy. It is possible also that under the influence of pregnancy, a cerebral process may develop symptoms it does not have outside of pregnancy. The author thinks that the peculiar attacks in the case of metencephalitis can be explained in this manner.

Acetonitrile Test in Pregnancy—Sommer found that the acetonitrile test, which indicates the presence of thyroidal substances, is strongly positive in the serum of women during the last months of pregnancy. The serum of women with eclampsia likewise was positive, but not quite as strongly as that of healthy pregnant women. The serum of women with genital carcinoma and of healthy nonpregnant women conferred no protection against acetonitrile poisoning, that is, the test was negative. Various preparations of the anterior hypophysis extracted from the urine of pregnant women, protected the test animals against acetonitrile, however, these tests were not as strongly positive as those obtained with the serum from women who are in the last stage of pregnancy. The author concludes that the acetonitrile test in the serum of pregnant women is highly positive because the urine contains not only the thyroidal hormone but also the thyrotropic hormone of the anterior hypophysis.

- Operations on Brain Ventricles and Choroid Plexus. V. N. Shamov — p. 135

Experimental Thrombophlebitis—Shevkunenko states that arrest of the blood flow in a vein fails of itself to cause thrombosis. Blood in a vessel between two ligatures does not coagulate. Alterations in the blood itself play a more important part in the thrombus formation than alterations in the vessel wall or slowing of the current. The latter in many instances is a secondary phenomenon. Thrombosis is not caused by a lesion of the vessel wall. It has its origin in the alterations of the blood, its localization being determined by the lesion in the vessel wall and by slowing of the blood current. Thrombosis frequently is a local manifestation of a general disease condition. Multiple thrombi are not necessarily the result of an embolic distribution from a main focus. They may represent multiple manifestations in various parts of the body of a general disease condition. The author produced experimental phlebitis

and thrombosis with the use of ferrous chlorate or a culture of hemolytic streptococcus. The inflammatory process extended from the adventitia to the media and intima, when a thrombus formed. He found it difficult to reverse the order of extension. The thrombotic process extends along the course of the vein as a periphlebitis along the perivascular lymphatics and along the vasa vasorum. Ligation of the vein close to the thrombus fails to arrest its spread. Ligation of the vein in advance of the production of the experimental thrombus likewise failed to prevent its spread beyond the ligature, even when, in addition to the ligation, the vein was cut across. Thrombosis extended along the main trunk in the direction of the venous current. The effect of added trauma and infection was to enlarge materially the field of thrombosis so as to involve the collateral branches. Better results were obtained when the vein was ligated some distance from the thrombus. Excision of the inflamed vein gave still better results. Bleeding into the bed of the vein acted as a contributing factor in thrombus formation. Loss of blood had the same effect. Because thrombosis results not only from local but also from general conditions, and particularly because of alterations in the blood, the author considers it advisable to limit, so far as possible, all therapeutic intravenous injections.

Infection in Postoperative Thrombosis—Korganova-Müller studied the role of infection in the origin of postoperative thrombosis and embolism in the necropsy material of the pathologic institute of the Babukhin Clinical Hospital in Moscow. Among 4,621 necropsies performed during six years, there were found 72 instances of thrombosis and 41 of embolism (7 fatal). The annual variation in incidence was well within the limits of error and chance. Embolism was the cause of death in 0.15 per cent of all necropsies and of 0.55 per cent of postoperative cases. In 86.3 per cent of cases of thrombosis and embolism necropsy revealed the presence of a general or a local infection. Infection was present in 93.6 per cent of the surgical material. Operations on the gastro-intestinal tract and the female genitalia furnished the largest number of thrombosis and of embolism. The period of predilection was between 40 and 70 years. In surgical material, however, thrombosis and embolism occurred in younger patients as well between the ages of 20 and 50, while in the medical material the ages of the patients were from 45 to 80. Diseases of the cardiovascular system and of the parenchymatous organs and the malignant neoplasms occupied the first place among the accompanying disorders, while in the postoperative material the most frequent associated diseases were infection and malignant neoplasms. The author concludes that of the numerous factors infection plays the leading part in the causation of postoperative thrombosis and embolism. Its effect is to be seen in a direct bacterial damage to the vessel wall and in the physicochemical changes of the blood as well as in the effect of toxins and ferments on the organs and tissues and on the organism as a whole.

Removal of Parathyroid Glands in Fibrous Osteodystrophy—Terebinskiy states that the question of localized fibrous osteitis and of the generalized form representing two stages of the same disease has not been definitely answered. It has been pointed out that an enlargement of one or more parathyroid glands is always present in generalized osteodystrophy, whereas it was never noted in the localized form. To the twenty-eight cases collected by Hunter in 1931 the author was able to add eleven more by the end of 1932, in which the parathyroid glands were investigated because of generalized fibrous osteitis. Analysis of the thirty-nine cases showed that enlargement of one or more parathyroid glands was present in twenty-nine. The enlargement was due mainly to adenomatous hyperplasia and in only one case to malignant adenoma. Removal of hyperplastic parathyroid tissue resulted in more or less improvement in twenty-two. In these cases the abnormally high blood calcium returned to normal, the inorganic phosphorus in the plasma rose from an abnormally low level to normal and there was an improvement in general health, gain in weight, disappearance of bone pains, more rapid healing of fractures and ability to walk. In eight cases the parathyroid glands were found to be unaltered. Apparently generalized osteodystrophy may exist in the absence of parathyroid hyperplasia. The experience in these cases showed that removal of normal parathyroids sometimes aggravates the course

of the disease. In the author's case a single unaltered parathyroid gland was found in the neighborhood of the left lower pole. He did not remove it. Two nodes were removed from a colloid goiter. These proved to be thyrogenous tissue. Five months later there was a marked improvement with lowering of blood calcium, arrest of osteoporosis, absence of new foci and improvement in the roentgenologic appearance of the involved bones. The author is at a loss to explain this improvement, except on a supposition that the removal of adenomas from the thyroid had a beneficial effect on the thyroparathyroid function.

Etiology and Pathogenesis of Cerebrospinal Meningitis—According to Tsekhnovitsner and Popova, the meningococcus of Weichselbaum, the causative agent of cerebrospinal meningitis, while displaying a special predilection for pia membranes, is capable of provoking lesions in various other tissues. For this reason attention must be directed to the general meningococcal infection rather than to meningitis alone. It is important not to limit oneself to the bacteriologic diagnosis of the Weichselbaum meningococcus but to search for the associated organisms as agents of a mixed infection. The upper posterior nasopharynx is the portal of infection for the meningococcus. A mild, evanescent nasopharyngitis is produced by the meningococcus or associated bacteria. This nasopharyngitis gives rise to a hematogenous metastatic meningococcal infection of various organs and in particular of the cerebrospinal fluid, the pia mater of the brain and the brain substance itself, producing a purulent meningococcal infection. Invasion of the central nervous system takes place primarily by way of the capillaries of the choroid plexus and the pia mater. Purulent meningococcal encephalitis is the result of a secondary invasion from the cerebrospinal fluid of the ventricles. The direct passage of meningococci from the blood capillaries into the brain substance occurs only exceptionally. The modern literature presents no support for the theory of meningococcal infection of the central nervous system by way of the olfactory nerves. Effective serotherapy implies the use of an active type serum, a rapid bacteriologic diagnosis of the type of meningococcus and localization of the infecting organism, the earliest intraspinal administration in the case of meningitis and intramuscular administration in other forms of meningococcal infection, sufficient dosage and repeated injections of type serums. In the study of local epidemics it is necessary to study carefully the local types of meningococcus in order to develop specific antimeningococcus serums.

Microscopic Anatomy of Cerebrospinal Meningitis—Popova and Ovcharenko state that besides purulent meningitis the meningococcus not infrequently produces purulent encephalitis. Purulent foci may develop in various parts of the brain but are found most frequently below the ependyma of the ventricles. This localization of purulent foci supports the view that the meningococci invade the brain tissue by way of the cerebrospinal fluid through the ependymal layer of the ventricles. Besides the foci of suppuration there develop in the brain as the result of toxemia diffuse degenerative alterations of the brain cells. The degenerative changes of the brain cells are most marked in the region of the tuber cinereum and may in some cases be the immediate cause of death.

Psychotherapy in a Dispensary—In Platonov's opinion the dispensary unit is best equipped and adapted for the practice of psychotherapy as applied to broad masses of workers. The facilities and composition of a dispensary offer ideal conditions for psychotherapeutic work, closely bound up as it is with the study of personality as a whole from the biologic as well as from the sociological point of view. The modern concept of personality as a social biologic unit, the physiologic orientation

of psychotherapy, the discovery of the dynamics of the laws governing the higher nervous activity, the enlargement of the scope of psychoneurology all justify the introduction of psychotherapy as a part of the therapeutic and prophylactic sector of a dispensary unit. The study of the dynamics of the brain cortex facilitates the understanding of the realistic causes of development of mechanisms of pathologic reactions and simplifies analytic psychotherapy. It obviates the complicated muddled and utterly unreal psychoanalysis of Freud as well as of Adler constructed on subjectivism. It renders causal psychotherapy more accessible to an average psychoneurologist and at the same time more productive. Psychotherapy based on physiologic studies of the cerebral hemispheres must be entrusted to the psychoneurologist. It must be his task to popularize the psychotherapeutic ideas and the closely associated psychohygienic ideas. It should be his problem as well to direct the personnel of the dispensary along these lines.

- Aplastic Anemia (Frank). O. Knudsen—p. 164
- Subacute Aleukemic Myeloblast Leukosis. Case. N. I. Nissen—p. 165

Infectious Mononucleosis and Agranulocytosis.—The decisive diagnostic sign Bie says is the relation of the red blood corpuscles. No anemia of consequence is seen in infectious mononucleosis, while acute leukemia always and fairly rapidly produces a considerable and progressive anemia. Differentiation between the ulcerous anginas which are symptoms of infectious mononucleosis and those of other etiology is hardly possible at present. The most interesting contribution to the etiology of infectious mononucleosis is that of Nufeldt who from three patients having this ailment cultivated three identical bacterial strains which on injection in rabbits produced a disease resembling human infectious mononucleosis. Discussing agranulocytosis, the author emphasizes the importance of examining the leukocytes in every case of infectious disorder in which the diagnosis is not assured by other methods, especially with anginas of somewhat peculiar appearance. Agranulocytosis may occur as a primary idiopathic disturbance or as a secondary pathologic condition caused by infections or intoxications. Of infectious diseases, septicemia most often causes agranulocytosis. Toxic substances that produce it are benzene, arsenic combinations, especially arsphenamine, and bismuth combinations, agranulocytosis caused by roentgen rays, radium and thorium are also classed as due to intoxication. If the number of leukocytes is below from 500 to 800, or if the monocytes are entirely absent, the prognosis is poor, the greater the number of monocytes the better, and a considerable increase in monocytes, even to above normal, during the course of the disease is a favorable sign.

Agranulocytosis.—The five fatal cases observed by Holten and his associates in the last year and a half, all in women set in during hospitalization for other disorders. During the same time no patient was admitted with agranulocytosis. The only point of similarity in the history of the patients was found to have been treatment for a longer time with amidopyrine. From their cases and those of Videbeck and Madison and Squier the authors conclude that in all probability amidopyrine in therapeutic doses is, under circumstances not yet explained, capable of producing agranulocytosis. They have begun an experimental study to determine whether it is a matter of hypersensitivity to amidopyrine, primary dysfunction of the bone marrow with secondary effect of this drug or something wholly different. Conservatism in the use of amidopyrine and its numerous combinations at least over a longer period seems to some extent to be called for.

Infectious Mononucleosis in Sisters.—One of these two cases in sisters both living at home appeared one month before

the other and was hospitalized after two weeks. An indication, Olesen says, is thus afforded as to the period of incubation, which may apparently have been a month and was at least two weeks. A third case is also reported. The patients all gave positive reaction to heterophile antibodies, and in all the increase in mononuclear cells was due exclusively to a lymphocytosis.

Agranulocytosis Treated with Liver Extract.—In the first of Plum's cases of typical agranulocytosis, five days' treatment with, all told, 90 cc of liver extract intravenously and 60 cc of pentnucleotide was followed by a lytic but rapid fall of temperature, and pronounced increase of granulocytes, beginning on the third day of treatment, together with marked clinical improvement. Aggravation of the condition soon set in with fatal outcome, in spite of a leukocyte and granulocyte count above normal. The author thinks that he should perhaps, like Foran have continued the liver treatment after the pronounced increase of leukocytes. In the second instance energetic treatment with liver extract and pentnucleotide was without benefit.

- Hemorrhagic Diathesis as Result of Treatment with Sanoerysin. Case. A. Bie—p. 202

Antianemic Factor in Dried Stomach Substance.—Meulengracht states that excision of the material for these experimental preparations of swine stomach was made with due regard to the anatomic apportionment of the different glands in the stomach. Preparations from the pyloric glandular portion were highly active and those from the fundic glands inactive and the activity or inactivity of those from the cardiac glands is still an open question. Castle's "intrinsic factor" in the normal gastric juice thus seems to be connected with the pyloric glands (cardiac glands?). Human pernicious anemia is apparently due to atrophy and inactivity especially of the pyloric glands (cardiac glands?), i. e., is dependent on loss of a special function localized there.

Pepsin and Rennin Activity in Dried Stomach Substance.—Meulengracht and Schjødt found considerable pepsin and rennin activity in the preparations from the fundus and little in those from the cardiac and pyloric portion of the stomach of swine and conclude that pepsin and rennin are probably secreted by the fundus glands only. They established physiologic and anatomic dissociation between pepsin and the antianemic factor in the stomach. As the two substances are, however, both destroyed by about the same processes and same degree of heat, determination of the pepsin activity of a commercial preparation of whole stomach can with reservation be used as an indicator of its antianemic efficiency.

Medicolegal Examination of Stains in Determination of Type.—Therkelsen's experimental studies on the establishment of type A B in blood stains show that the diagnosis of type B in blood stains must be made with reservation even if the absorption for the B receptor is strong, as an unestablished A receptor may be present at the same time. Medicolegally, he says, establishment of a B receptor in blood stains calls not only for the statement that the stain is presumably from a person of B type but for the added statement that it may belong to a person of type A B. He describes a method for the establishment of the M receptor in blood stains, based on the attainment by gradual addition of anti-M serum to the stain substance of an agglutinin level raised just far enough beyond unspecific binding so that specific binding will clearly appear. The direct medicolegal significance of establishment of the M receptor is stressed, also its indirect value as an aid in the diagnosis of type O.

ABDOMINAL PAIN

II THE SENSITIVE REGIONS IN THE ABDOMEN AND WAYS IN WHICH THEY MAY BE STIMU- LATED TO PRODUCE PAIN

WALTER C. ALVAREZ, M.D.
ROCHESTER, MINN.

It is sad to have to admit today that, with all the facilities of modern medical diagnosis at his disposal, the best of clinicians is still unable to explain many an abdominal pain. He can somewhat justify his ignorance so long as 2 inches of skin and fat and muscle lie between him and the apparent seat of the trouble, but what is he to say when the surgeon looks up after a careful exploration and announces that he has been unable to find any sign of disease? Should the physician then wash his hands of the problem by questioning the reality of the pain which he cannot understand? Should he comfort himself by calling it "nervous," or should he not bestir himself to search for new microscopic or perhaps purely chemical causes for it? Should he not more resolutely face the fact that severe pain can arise in tissues that do not show any gross organic disease?

It was with the hope of learning something about the mechanisms of obscure types of abdominal pain that a few years ago I began a search through the writings of anatomists, physiologists, neurologists, neural surgeons, students of local anesthesia, experimenters, and careful observers everywhere for suggestions regarding the ways in which nerve endings might be stimulated and painful messages might be carried to the brain. The present paper is one of a series which I hope to write as I review what little I have been able to glean in the library, in the laboratory and in the consulting room.

SENSORY PATHWAYS LEADING AWAY FROM THE ABDOMEN

In the first paper of this series (1931) I¹ showed that nearly all the sensory nerves from the organs in the upper part of the abdomen and from the small bowel and the visceral peritoneum travel to the posterior root ganglions of the dorsal spinal cord by way of the major splanchnic nerves. A few afferent fibers go out by way of the phrenic nerves² and a few more may perhaps

accompany the vagus nerves,³ the aortic plexuses⁴ and the lateral sympathetic chains.⁵

Sensation from the lower abdominal organs reaches the spinal cord by way of many paths, some of which are still poorly mapped. One difficulty in the way of studying them is that they vary in different individuals. There are many connections between the lateral ganglionated chains and the central plexuses, and also some connections between the sensory nerves in the pelvis and those in the upper part of the abdomen. One of the most important nerves in the lower part of the abdomen is the presacral nerve, which carries most of the afferent fibers coming from the pelvic organs.⁶ Bradford Cannon has shown with his ingenious technique that in the cat the abdominal vagus and the distal parts of each lumbar sympathetic chain are without sensation.⁷ In man, stimulation of the lumbar sympathetic chain causes pain in the leg and ankle.⁸

An important point brought out by Hoffmann is that the splanchnic nerves are not necessarily involved in the production of the tense abdomen of peritonitis. In this disease, the rigidity of the muscles appears to be due to impulses reaching the spinal cord by way of the lower intercostal nerves.

NATURE OF SENSORY NERVES IN THE ABDOMEN

For some time the generally accepted view has been that the sensory nerves supplying the abdominal organs are no different from those elsewhere in the body. They run to the posterior root ganglions, and in spite of the fact that they are found in the same sheaths with the sympathetic nerves they do not belong to the autonomic or involuntary system. Recently, evidence has been accumulating to strengthen the view that involuntary nerves may also have something to do with the production of pain. Thus, Bruning and Gohrbandt showed

that nicotine injected into the celiac ganglions will abolish abdominal sensation,⁸ and similar observations were made by Davis, Pollock and Stone.⁹ If one accepts the usual interpretation of the action of nicotine, one must assume that any pain blocked in this way was being carried by a pair of sympathetic neurons connected by a synapse. The experiments were so clear cut and so well controlled that, although I have little faith in deductions based on the effects of poisons, I believe the questions raised must be faced squarely. Incidentally, some anatomic basis for the conception of sensory nerves in the involuntary system has been found by Lebedenko and Brjussowa.¹⁰

In a recent thought-producing article, Shaw¹¹ emphasized the point that during the course of an operation under local anesthesia the pinching of a sympathetic ganglion causes severe pain, but only after a definite interval of time in which irritable chemical substances are probably formed. As Cannon,¹² Gerard¹³ and others have pointed out, there is now much evidence to show that impulses reaching tissues by way of nerves produce chemical substances which spread out and affect not only muscles but also nerves. It is possible that some of these substances can produce pain.

It has been observed also that after sympathectomy the region affected will sometimes be markedly hyperesthetic for several weeks, and Shaw and Pette¹⁴ have suggested that the cause of this is a removal of inhibition and a lowering of the threshold for pain. Craig, however, is inclined to look on this sensitiveness as due more to neuritis following the inevitable slight trauma done to somatic nerves during the operation.

In favor of the view that involuntary nerves carry painful sensations is the fact that some intractable types of pain can be relieved, at least for a time, by sympathectomy. Unfortunately, only the future can tell how lasting such cures are going to be, and until the evidence is in, opinion as to the sensitiveness or insensitiveness of true sympathetic nerves is likely to be divided.

It is possible that injury to or disease of the involuntary nerves can so alter the circulation or the metabolic processes in a region that pain results. Another possibility is that there may be afferent sympathetic or connector fibers which, if they do not carry actual sensations of pain, at least carry impulses which are painful when transmitted to other neurons. As Thies¹⁵ and others have pointed out, a diseased gallbladder, a peptic ulcer, or a kidney stone can produce many distressing symptoms other than pain.

THE SENSITIVE AND INSENSITIVE REGIONS IN THE ABDOMEN

In any analysis of the problem of abdominal pain the student must begin with a clear understanding of the

following facts. First, that the viscera and the visceral peritoneum contain so few sensory nerves that they are insensitive to most stimuli such as those produced by cutting and pinching and burning. Second, that what few nerves there are in the viscera and mesenteries are closely associated with the arteries. Third, that the parietal peritoneum, which is well supplied with afferent fibers, mainly from the intercostal nerves, is everywhere highly sensitive.

No good work could be done until physiologists learned to devise their experiments in such a way that they could be sure of stimulating an organ without, at the same time, pulling on its mesentery or injuring highly sensitive arteries or folds of parietal peritoneum.

THE ORIGINAL SEGMENTAL DISTRIBUTION OF SENSORY NERVES IN THE ABDOMEN

Before attempting any study of abdominal pain, and particularly of its mode of reference to the surface of the body, it is essential to review the original segmental distribution in the embryo of the sensory nerves to the stomach and intestine, and to the organs that arise as buds from the upper part of the primitive gut. Because of the well known shift caudad of the organs in relation to the spinal cord one finds that at birth the segments concerned with the nerve supply of the digestive tract range from the sixth thoracic, corresponding to the level of the stomach, to the twelfth thoracic, corresponding to the level of the ileocecal sphincter.¹⁶ It is this old arrangement that accounts for the fact that pain arising in the small intestine is felt around the navel, and that pain arising in the colon is usually felt in the lower half of the abdomen. To be sure, the work of Jones and Pierce¹⁷ indicates that pain due to distention of the cecum or of the hepatic and splenic flexures of the colon is likely to be felt at points in the abdominal wall almost overlying the segment irritated, but this may be due to pulls on folds of parietal peritoneum.

It can easily be seen now why so often the first colicky pain in an attack of appendicitis is felt around the navel, whereas the second, steady pain, due presumably to involvement of parietal peritoneum is felt in the right lower quadrant of the abdomen. The shift is due to the fact that a more distally situated set of nerves has become involved. In cases of ulcer, and particularly of jejunal ulcer, similar shifts of pain due to slow perforation or to extension of infection can often be seen during the course of the disease. Rivers¹⁸ is now making a particular study of these shifts and of their great diagnostic value.

The anatomist can again be helpful to the clinician when it comes to explaining why pains arising in embryologically different parts of the diaphragm are referred to different parts of the body¹⁹ or why pain arising in the kidney can be felt in the testis but not in the scrotum.

SENSORY ENDINGS FEW AND FAR BETWEEN

The great insensitiveness of all the abdominal viscera seems to be due to the fact that they are poorly supplied with sensory nerve endings. Because these

endings are so far apart it is probable that a knife or hemostat, or even a glowing cautery, reaches so few that the stimulus is subliminal. Conditions are somewhat as they are in some parts of the skin where a morphine addict can find small areas in which the insertion of the needle is painless.

Obviously, then, if a stimulus applied to an internal organ is to produce pain, it must be spread over a considerable area, a long segment of bowel must contract powerfully, or a wide area of visceral peritoneum must be irritated. Only in this way can one explain some of the curious observations that have been made. Thus, Balfour has told me of resecting a stomach under infiltration anesthesia of the abdominal wall. The patient lay uncomplaining while the stomach was cut and burned and sewed, but he rose up and protested vigorously when the peritoneal cavity was washed out with warm physiologic solution of sodium chloride.¹

Some physiologists have suggested that stimuli such as pinching, sticking, cutting or burning are not adequate for or suited to the production of pain, perhaps the nerve endings are so constituted that they do not react to a single stimulus but only to oft repeated ones. Some such explanation seems to be needed at times to explain the curious fact that organs which can be so insensitive to some types of stimulation can be the seat of such severe pain.

As one would expect, the Vater-pacnian corpuscles, which are supposed to represent the commonest type of sensory nerve ending in the abdomen, are fewest and farthest apart in the most insensitive regions of the abdomen, and they are most numerous in the regions which the surgeon has learned to handle with care. They are found on the walls of the arteries²⁰ and this helps to explain the well known sensitiveness of the lesser omentum, the root of the mesentery, the foramen of Winslow and the cleft of the liver. Larger arteries are said to be more sensitive than small ones, and, as one would expect from this, the larger ones are supplied with the greater number of nerve endings. Actually it has not been easy to find sensory endings in vessels smaller than 60 microns in diameter.²¹ As every clinician knows, the abdominal aorta is highly sensitive in some persons, and some types of pain seem to arise in it. In operations on the gallbladder, done under local anesthesia, it is the tying of the cystic artery that usually hurts most. Veins are less sensitive than arteries, and they carry fewer nerve endings.

The work of Sheehan showed that the Vater-pacnian corpuscles lie in peculiar groups on the head of the pancreas and in the capsule of the mesenteric lymph nodes. In the cat there are three times as many in the mesentery of the small intestine as in the mesocolon. More are to be found near the base of the mesentery than near the bowel, and there are many more in the region of the duodenum and jejunum than around the ileum.

The Vater-pacnian corpuscles are commonly supposed to respond to pressure, but the researches of Ramström²² made this appear doubtful. He made small

incisions in the abdominal wall and, inserting the finger, palpated the parietal peritoneum. In many cases even heavy pressure could not be felt, but sometimes it caused a colicky pain. Rubbing always caused distress.

It is probable that not all sensory nerve fibers end in corpuscles, and several variants have been described.

DIFFERENCES IN DIFFERENT PERSONS

One great difficulty in studying abdominal pain arises in the fact that different individuals vary markedly in their sensitiveness, and even one individual will vary in his response from time to time and under different conditions. The same difficulty is found in individual animals and in different species. Thus, Kast and Meltzer found it more difficult to study pain in cats and rabbits than in the dog. Furthermore, as Farr²³ has pointed out, observers differ in their conclusions because some are rough and others are gentle in their handling of the abdominal organs. One surgeon will slowly close a clamp on the mesentery of the appendix and conclude that this tissue is insensitive, while another will close the clamp quickly and thereby cause severe pain.

According to Farr,²⁴ Lennander,²⁵ Hesse,²⁶ Morley²⁷ and others, the insensitiveness of the abdominal organs is not necessarily altered by inflammation or congestion, but Kast and Meltzer²⁸ and others found that an inflamed segment is more sensitive than a normal one. Obviously, this comparison must often be difficult to make.

THE SENSITIVENESS OF THE PERITONEUM AND THE MESENTERY

As I said before, one of the first things that the student of abdominal pain must do is to get clearly in mind the difference in sensitiveness between parietal and visceral peritoneum. This is brought out clearly during a herniotomy under local anesthesia, when the insensitiveness of the intestine will be in marked contrast with the decided sensitiveness of the neck of the sac.

When operating under local anesthesia, the surgeon must always handle the parietal peritoneum with care. It must not be pinched or pulled on, and sponges must not be pulled out past it. On the other hand, a sponge may be removed painlessly from between two loops of bowel. As one would expect, the breaking of adhesions between bowel and abdominal wall is likely to cause pain, while adhesions between loops of bowel are insensitive.²⁸ It is not surprising, then, that traction on all those ligaments which are formed from or invested with parietal peritoneum is painful.

The excruciating pain under the right leaf of the diaphragm which comes when a liter or two of air or other gas is injected into the abdominal cavity is probably produced by the resulting separation of liver and diaphragm and the tension this puts on coronary and falciform ligaments.

Lennander²⁹ suggested that pain might be produced by the pressure of a gas-filled loop of bowel against parietal peritoneum, and particularly by the often distended splenic flexure pressing up against the diaphragm. The objection to this theory is that a markedly dilated splenic flexure is often seen by the roentgenologist in persons who are perfectly comfortable.

The perforation of a gallbladder against the visceral peritoneum surrounding a loop of bowel need not be productive of pain, but perforation of a jejunal ulcer against the root of the mesenteric fan or against parietal peritoneum is usually painful.

Most of the pain produced by gaseous distention of the bowel is supposed to be due to tension on mesenteric attachments and arteries, and all surgeons who operate under local anesthesia agree that mesenteries must not be pulled on if pain, nausea and vomiting are to be avoided. Since the nausea is produced even in patients under spinal anesthesia, the pathways are probably in the vagus nerves. A puzzling fact is that marked distention of the intestine which one would think would produce a pull on the mesentery is often painless.

The Omentum—The greater omentum seems ordinarily to be insensitive except in the neighborhood of the larger arteries. Occasionally it is sensitive, and pain can be felt when portions are tied off (Neumann,³⁰ p 486).

Peritonitis—As one would expect, the pain produced by the escape of acid gastric content into the peritoneal cavity is terrific, and so is the pain produced in animals by the injection of 1 cc of turpentine.³¹ In man the intraperitoneal injection of a little vaccine made from colon bacilli or streptococci will produce the clinical picture of an acute generalized peritonitis.

One would expect to find peritonitis always very painful, but this is not the case. As C. F. Dixon has pointed out to me, there is a type of fulminating generalized peritonitis in which the symptoms are those of shock, combined with almost unbearable pain. In other cases an appendiceal abscess, walled off by loops of bowel, will suddenly leak and throw the patient into spasms of pain. Strange to say, simple drainage of such an abdomen will often put a stop to the pain although the inflammatory exudate is still spread widely over stomach, bowel and liver. In other cases generalized peritonitis will be painless, or peritonitis that began with pain will later become painless. Similar observations have been made in animals,³² and it seems probable that nerve endings are so exhausted or so severely injured that they can no longer respond. In some cases cessation of pain may come with the cessation of all movement in the intestine. It may be like the cessation of pain that comes when an inflamed joint is immobilized. It is worth noting that Hoffmann, in his experiments, was able to produce a rigid contraction of the abdominal muscles only when he stimulated parietal peritoneum.

INSENSITIVENESS OF MOST OF THE ABDOMINAL ORGANS

The Stomach and Duodenum—The stomach is so insensitive to cutting that it can easily be resected under

local anesthesia. The gastric mucosa is normally insensitive to 0.5 per cent hydrochloric acid,³² it is insensitive to strong faradic stimuli, and it is only slightly sensitive to irritants such as strong alcohol, pepper and mustard. Neumann (footnote 30, p 495) told of a man who swallowed 3 Gm of finely ground white pepper and noticed only a feeling of warmth and later some burning. According to Muller³³ the severe gastritis that is produced by the swallowing of escharotic poisons is not painful, and it is known that the gastritis that precedes or is commonly associated with cancer of the stomach is usually unaccompanied by symptoms.

As every brewery employee and every patient with severe diabetes insipidus knows, the stomach will tolerate a great deal of distention without the production of pain. Kinsella,³⁴ Apperly and other investigators have drunk water in large amounts as fast as they could get it down, but only with difficulty could they produce gastric discomfort. Even acute dilatation of the stomach is commonly painless. Occasionally distention of the stomach by a large meal seems to produce pain, but this may be due to pulls on bands running from the stomach to the diaphragm, spleen and parietal peritoneum. Patients with marked enlargement of the spleen can also be made very uncomfortable by a full meal.

A discussion of the modes of production of pain in cases of gastric and duodenal ulcer would take up so much space that I must reserve the topic for another paper. All I will say here is that in spite of much research there is as yet little agreement among workers. It is easy to say that the pain is due to the etching effect of the acid or to exaggerated peristalsis, but serious objections can be made to both of these theories. Thus, no one can as yet explain why a man without any defect in the gastric and duodenal mucosa demonstrable at operation or necropsy can have typical ulcer pain relieved by alkalis, while another man with a big florid ulcer can be free from symptoms. All I feel sure of is that, whatever the mechanism of ulcer pain may be, it can be turned on or off within an hour, perhaps by some sudden change in the irritability of the gastric nerves.

The Small Bowel—The mucous lining of the small bowel is largely insensitive, as any one can see from the fact that the ulcerations of typhoid, tuberculosis and carcinomatosis are rarely painful until to the defect in the mucosa there is added either obstruction of the lumen of the bowel or else perforation of the wall. As Lennander²⁹ and Muller³³ have shown in patients with an intestinal fistula, faradic stimulation of the mucous membrane does not produce pain.

The tormina or severe griping pains seen with dysentery and cholera are due probably to contractions of the bowel. Mackenzie, while operating under local anesthesia, noticed that the patient felt pain when a loop of small bowel contracted, but others have remarked on the fact that powerful contractions can be painless. Maylard³⁵ has recorded the case of a physician with a mulberry stone in the substance of the kidney who

suffered with attacks of intestinal colic which apparently was reflex in origin. There was agonizing pain, which seemed to be due to contractions, traveling down the bowel and ending in tenesmus and the passage of flatus. Cycles of such pain followed one after another. Hugh Cabot tells me he has seen many instances of this type of "reflex."

Snell has reminded me also of the intestinal distress seen commonly in patients who are being fed through a fistula into the jejunum or who are learning to eat slowly after having submitted to subtotal gastrectomy. In them the pain due to distention or abnormal contraction, or perhaps to widespread stimulation of the mucosa, is accompanied by nausea, sweating and sometimes symptoms of mild shock.

My impression from personal experience is that although the small bowel is normally insensitive, there are times, as after the eating of irritant food, when the victim will become conscious of peristalsis and will say that he can feel the food passing over sore places in the bowel.

Ways of Causing Pain in a Hollow Organ—There seem to be three main ways of producing pain in a hollow organ: one is by stretching the muscular wall, another is by causing it to contract powerfully, and another is by pulling on its mesenteric attachments. The work of a number of investigators indicates that neither distention nor contraction of the bowel will produce pain unless the mesenteric fan is pulled on,³⁷ but other observers, while admitting that a pull on the mesentery is a common cause for pain, have shown that it is not the only one, and that distention of the muscular wall alone will cause distress.³⁸ As these men pointed out, the mesentery will tolerate, without causing pain, degrees of stretching that are not seen with ordinary distention or contraction of the bowel. Unfortunately, it is still hard to explain why, at times, marked bloating is painless when at other times the presence of a little gas in the bowel causes great distress.

According to Ryle,³⁹ the severity of mechanically induced pain is in inverse proportion to the normal distensibility of the viscus. This, perhaps, can account for the fact that the most severe pains are produced when fairly thick-walled tubes with a small lumen such as the ureter, appendix, bile ducts or uterus are affected.

Powerful Peristalsis Not Always Painful—Most physicians will probably think of intestinal pain as being due to cramplike contractions of the muscle in the wall of the bowel or to exaggerated peristalsis, and yet, when they stop to consider, they must remember that the lively peristalsis that is produced by purgation, or the powerful waves that can be seen traveling over the stomach in cases of congenital pyloric stenosis or of cancer of the pylorus, or over the colon in cases of Hirschsprung's disease or of cancer of the sigmoid flexure, are usually so painless that the patient is not even conscious of them.

Obviously there must be some extra factor present to produce pain, and this I suspect is an incoordination of peristalsis which leads to the conflict of waves and the putting of pressure on accumulations of food or gas in between. A wavelike contraction, no matter what its amplitude, is probably painless just so long as the

walls of the viscus do not meet to produce water-tight or air-tight rings. Such tight rings approaching one another will put pressure on the contents of the tube and on the nerve endings in the wall. I once happened to swallow just as a wave of regurgitation started up my esophagus and when the two contractions met I felt a most unpleasant tearing feeling back of the sternum. Some of my friends have had similar experiences.

One type of pain is produced apparently by the failure of sphincters to relax at the proper time. Some pains in the upper part of the abdomen are supposed to be due to pylorospasm, and I believe that some of the pains that come at 11 a. m. and 4 p. m. are due to efforts made by the terminal loop of ileum to force its content past a contracted ileocecal sphincter. In such cases the taking of more food turns the tide in favor of the ileum, and this brings relief. Occasionally, one will find severe pain in the upper part of the abdomen associated with cardiospasm,⁴⁰ but what the mechanism is no one knows.

According to some investigators, the powerful contractions that can be produced in the bowel with the help of the faradic current or by the injection of barium chloride are not painful unless a sufficiently long segment of intestine is involved, or unless blood vessels are constricted or the mesentery is stretched.⁴¹

It is perhaps just as hard to explain why some powerful intestinal contractions produce pain and others do not as it is to explain why a cramp in the leg is painful when the more powerful contraction of the same group of muscles during a tug of war does not cause discomfort. In fact, the best way in which to relieve a cramp in the leg is to contract the muscles voluntarily, and some research workers have even suspected that contraction of the muscle of the gastric or intestinal wall will at times counterbalance the pull on nerve endings produced by distention and will thus relieve pain. Lewis⁴² and his associates collected much evidence indicating that constant pain can be produced by rhythmic muscular contractions whenever an insufficient blood supply leads to the formation of toxic and nerve-irritating substances.

Distention of an organ need not be painful so long as it is brought about slowly. This is probably the explanation for the absence of distress in many cases of Hirschsprung's disease and hydronephrosis.

The Appendix—The appendix is insensitive to cutting, crushing and cauterizing, but some patients operated on under local anesthesia can feel the tightening of the purse-string suture, and they usually can feel the tying of the ligature on the meso-appendix,⁴³ especially if the least pull is made on it. Traction on the mesentery of the terminal segment of ileum will sometimes produce the epigastric or umbilical pain that patients complain of at the beginning of an attack of appendicitis, and manipulation of the mesentery of the appendix usually produces nausea and retching. According to Harris,⁴⁴ pericecal membranes are usually insensitive, but any traction exerted on them resulting in a stretching of the parietal peritoneum will cause pain.

It is still far from clear why a diseased appendix causes pain. The fact that the first distress is felt in

the region of the navel suggests that the disease begins within the organ and affects the nerves that go out by way of the mesentery and the splanchnic nerves. Later, when the pain is in the right lower quadrant, the supposition is that the parietal peritoneum and a new set of nerves are involved. According to Hurst,⁴ the diseased appendix when palpated through the rectum is very tender.

So far as I know, no one has puzzled sufficiently over the fact that often, in appendicitis, when things are still going badly within the abdomen, the pain lets up. The usual explanation is that the appendix has "burst", but I wonder if this is a good word to use. So far as I can learn, the appendix perforates because part of it has become necrotic and not because it has been blown up like a toy balloon. If the apparent improvement were due to a release of pressure within the appendix, one should expect it to be the pain around the navel that stops, and after this one should expect a new, peritoneal, pain to appear around McBurney's point. Actually, my impression is that the pain that lets up and gives the patient a false sense of security is usually the one in the right lower quadrant. Perhaps in such cases something happens to bring insensitiveness to the peritoneal nerves. As Amberg⁴⁶ has suggested, it may be that the edema produced by infection can at times serve as an anesthetic much as does the edema produced by the surgeon when he injects saline solution into the skin.

In view of the marked insensitiveness of the appendix to cutting and crushing, it is hard to guess what change in it can account for the pain that is felt in the center of the abdomen. One can think of distention of the lumen or contraction of the muscle, or perhaps the formation of substances that irritate nerve endings. Because the meso-appendix is so sensitive to tension, Hesse²⁰ expressed the belief that the pain is due to stretching of this membrane brought about by the swelling or bending of the appendix. There must also be abnormal contractions in the adjacent ileum or cecum, contractions which often give rise to the vomiting of large amounts of intestinal fluid. Pain may be felt in regions distant from the appendix when there is extension of the inflammation along lymphatic channels.⁴⁷ Finally, as Mackenzie pointed out, symptoms such as rigidity of the psoas muscles and irritation of the ureter, bladder and uterus may be produced reflexly. He was once much impressed by the fact that, in a case in which symptoms of irritation in the pelvis were marked, operation showed that the appendix was nowhere near the bladder, uterus or psoas muscle.

If the present-day understanding of a dual sensory nerve supply to some parts of the intestine is correct, a physician, when faced by the common problem of chronic pain and soreness limited to the right lower quadrant of the abdomen, should actually refuse to think of appendicitis and should look more for disease in the peritoneal attachments of the cecum. If only because in one of my cases the pain and soreness in the right flank remained not only after appendectomy but also after excision of the right half of the colon, I always think of disease somewhere along the nerve tracts that supply the peritoneum in the region of the cecum. Theoretically, if smoldering disease in the appen-

dix can produce pain anywhere, it should be felt where it commonly is felt, around the navel or in the epigastrium. Another reason for the radiation of appendiceal pain to the epigastrium may be that the functions of the stomach, duodenum or small bowel are disturbed secondarily to disease in the right iliac region.

The Colon—In view of the complete insensitiveness of the colon when it is brought up into a wound, as in the formation of an artificial anus, it is remarkable how much discomfort and pain this part of the intestinal tube can cause many nervous women, and how much tenderness is complained of when it is rolled under the fingers. In two patients with a fistula into the cecum, Lennander⁴⁸ found the mucous membrane to be insensitive. Rutherford,⁴⁹ who studied another patient with a cecal fistula, found that any attempt to pass a sound or a finger through the ileocecal sphincter caused unbearable pain, due probably to distention of the muscle.

As every proctologist knows, the mucous membrane of the rectum and sigmoid flexure is insensitive to cutting, crushing or burning. Patients protest only when one pulls on the attachments of the bowel, and then they feel the pain or distress in the left lower quadrant of the abdomen.

The pain of diverticulitis may be due partly to spasm of the colonic wall, partly to obstruction of the lumen, and partly to the irritant effects of inflammatory products on nerves in the parietal peritoneum.

Kinsella³⁴ and others who have watched the colon during the giving of a barium enema have seen powerful contractions which were associated with pain. It is most important from a diagnostic point of view to note that all those who have observed such pains agree that they are felt only in the lower part of the abdomen, below the navel.

In the case of mucous colitis, it may well be that toxic or irritant substances are excreted from the blood into the mucosa. Sometimes the pain will stop following the exclusion of a few hurtful substances from the diet.

The Gallbladder and Bile Ducts—The method of production of gallstone colic and other types of pain in the biliary tract is so poorly understood and there is so much to be said about the subject that I cannot go into it fully at this time. All I shall say is that experiments have shown, both in animals and in man, that the gallbladder is insensitive to crushing or cutting. Sudden distention of the organ will produce some of the feelings of bloating and indigestion that are so annoying to patients with cholecystitis, but usually not the pain.⁵⁰ The common duct is much more sensitive, and distention here will produce pain, nausea, vomiting and that difficulty in breathing which is so characteristic of biliary colic. The puzzling feature is that the pain produced in experiments on human volunteers was usually epigastric and did not radiate typically to the back.⁵⁰

There are several reasons, then, for believing that the pain in the back must be due to some irritation, perhaps inflammatory in origin, of nerves that go out by way of the posterior parietal peritoneum. It is possible also that during simple distention of the uninfamed

biliary tract the experimenter does not stimulate those particular fibers in the splanchnic bundle which, on arriving in the dorsal region of the spinal cord, send out impulses to sensitize the region under the right scapula.

Because biliary colic can be seen commonly in the absence of gallstones, in the absence of a gallbladder, and even in cases in which most of the common duct has been destroyed by scarring I have wondered if at times it could be due to powerful muscular contractions in the pars pylorica of the stomach or in the first portion of the duodenum. This does not seem probable, because irritation of these regions by ulcers produces such a different type of pain with a different point of reference and a different type of radiation. One suggestive observation is that of Bloomfield and Pollard,⁵¹ who blew up a balloon in the third portion of the duodenum of volunteers and found that this sometimes produced pain with a distribution like that of biliary colic. Obviously, further observation and experiment are needed in this field.

Liver, Spleen, Pancreas and Kidney—All observers agree that the parenchyma of these organs is markedly insensitive. As a result, abscesses and infarcts are usually painless unless the organ is rapidly distended, or unless inflammation or irritation reaches nerves in the parietal peritoneum or along the arteries. Thus in the case of the liver, passive congestion that arises suddenly, as in an attack of paroxysmal tachycardia, or the rapid growth of a gumma or an echinococcus cyst will cause pain, while the slow growth of huge carcinomatous metastatic growths may take place silently.⁵²

There are reasons for believing that, in some of the cases in which extensive injury has been done to the liver by poisons such as arsphenamine or cinchophen, pain arises because of a widespread chemical stimulation of nerves. The objection to this theory is that in many cases severe hepatitis does not give the patient even local discomfort. While fully cognizant of the difficulties of my position, I still cling to the view that a liver that looks normal at operation can be the seat of severe pain, just as so commonly it is the seat of marked tenderness to palpation.

In the spleen, infarcts seldom cause pain unless they involve the diaphragmatic surface and produce adhesions to the parietal peritoneum. Barcroft, who has done much work on dogs with the spleen exteriorized and left uncovered outside the abdomen, told me that he has never seen any signs of pain resulting from manipulation of the organ.

The pancreas is usually an uncomplaining organ but it responds painfully to acute injuries and particularly to that acute form of inflammation which is accompanied by fat necrosis in the adjacent tissues. Carcinoma of the pancreas usually produces pain at some stage of the disease but I suspect that this comes usually when the growth invades other structures or blocks a duct.

In the kidney, pain is due usually to diseases that produce sudden swelling, such as acute glomerulonephritis, infarct formation or rapidly forming hydronephrosis. Strange to say, even the marked back pressure in the kidney pelvis that is produced when the ureter is inadvertently tied is often painless and in my experience Dietl's syndrome is rarely encountered.

Ureter—The ureter is tolerant of slow distention and it is often remarkably tolerant to the presence of a stone. At operation, pain is most likely to be produced when the peritoneal covering of the ureter is pulled on or traumatized.

Urinary Bladder—The urinary bladder is only slightly sensitive to ordinary laboratory stimuli,⁵³ but, as every one knows, distention, with the resultant muscular contractions, can cause pain. Muller⁵⁴ expressed the belief that the pain of tuberculous cystitis is due to muscular contractions. In operating under local anesthesia, much of the pain comes when the attachments of the bladder are pulled on.

The Uterus, Ovary and Tubes—The uterus is not very sensitive to cutting, and several writers (Neumann,⁵⁰ pp 411 and 708) have commented on the fact that in the past, when cesarean section had to be done without anesthesia, the incision through the uterus was not very painful. In operations under local anesthesia, much can be done to the uterus so long as its ligaments are not pulled on. The part of a curettement that is really painful is the dilation of the cervical canal. Severe menstrual pain seems to be due often to the efforts of nature to expel blood clots through this narrow channel. The powerful uterine contractions that occur during the later months of pregnancy are not distressing but, as every mother knows, the contractions of labor can be agonizing.

At operations under local anesthesia the ovary may be somewhat insensitive but the pedicle is often sensitive. During pelvic examinations the ovary itself is commonly sensitive to pressure.

ABDOMINAL LYMPH NODES

Although in many cases the abdominal lymph nodes become inflamed or enlarged without producing symptoms, in others such inflammation appears to produce soreness and pain.⁵⁴

CELIAC GANGLIONS

According to some writers the celiac ganglions are very sensitive, and according to others they are not (Neumann,⁵⁰ p 669). Their involvement in inflammatory masses due to the perforation of gastric or duodenal ulcers or their infiltration with carcinoma cells probably accounts at times for severe pain that bores straight through to the back.

It seems probable that there must be many cases of abdominal pain in which the trouble originates in disease of ganglions or nerves or nerve endings, but so far only an occasional one can be diagnosed. Most of the ganglioneuromas appear to be painless.

ABDOMINAL BLOOD VESSELS

Any one who has ever had to thaw out frozen fingers knows what excruciating pain can arise in tissues which for a time have been deprived of blood, and there are reasons for believing that not infrequently vascular disease or vascular spasm is a cause of abdominal distress and pain. The subject is too large to be treated adequately in the confines of this paper.

SOME USUAL CAUSES

I shall have to wait for another time to discuss the possible mechanisms that produce the severe pains seen

with some diseases of the abdominal nerves, with disease of the abdominal arteries, with giant urticaria and purpura and disease in the spinal cord and brain, disease in the thorax, diabetic ketosis, Addison's disease, acute generalized infections, malaria and lead poisoning

SUMMARY

The main sensory pathways out of the upper part of the abdomen lie along the major splanchnic nerves. Most of the sensory nerves in the abdomen probably do not belong to the autonomic system and are no different from those in the rest of the body. Evidence is accumulating to show that certain types of severe and intractable pain are due to some abnormality in the sympathetic nerves.

The abdominal viscera are insensitive to such stimuli as cutting, crushing and burning. The few sensory nerve endings present are associated mainly with arteries. The parietal peritoneum is everywhere well supplied with nerves. If a stimulus to an abdominal organ is to be sensed as pain, it must be applied over an area wide enough to affect many of the scattered nerve endings.

Much of the pain produced by distention of the bowel appears to be due to tension on the root of the mesentery.

The stomach is normally so insensitive to acids and other irritants that it is difficult to explain the pain of ulcer. As yet no one of the explanations proposed is adequate or satisfying. The salient fact is that at times the nerves appear to become so sensitized that pain can be felt even in the absence of strong acid or of a defect in the mucous membrane of the stomach and duodenum.

Pain is produced in a hollow organ when powerful contractions struggle to force material past an obstruction, it is produced also by rapid distention or by tension on the mesentery.

The distribution of sensory nerves in the abdomen follows somewhat the original segmental arrangement existing in the embryo. For this reason pain that arises in the stomach, duodenum and gallbladder is usually felt above the navel, and pain arising in the colon is usually felt below the navel. This point is helpful in diagnosis.

Pain arising in the appendix itself is usually felt around the navel, while pain arising in the peritoneal covering of the organ or in the cecum is felt in the right lower quadrant of the abdomen. Long continued pain and soreness around the cecum should suggest the presence not of appendicitis but of chronic perityphlitis or typhlitis, or of disease somewhere along the parietal (not mesenteric) sensory nerve tracts supplying the cecal region.

The mechanism of biliary colic is not clear. Such colic is seen in the absence of gallstones, in the absence of a gallbladder and, rarely, even in the absence of most of the common bile duct. Experimental distention of the gallbladder usually does not produce pain, but distention of the ducts does produce pain. What is puzzling is that, in most of the experiments that have been done this pain has not radiated typically to the right scapula.

The solid organs of the abdomen are so insensitive that the only thing that seems to cause pain in them is either rapid distention of the capsule or the extension of inflammation from them to adjacent parietal peritoneum.

It is suggested that some forms of abdominal pain are due to the accumulation of irritant metabolites or toxins in the tissues. Pain may also be caused by any disease or spasm in arteries which leads to injury of the tissues through the development of ischemia.

THE DIFFERENTIAL DIAGNOSIS OF ACUTE POLIOMYELITIS

M. BERNARD BRAHDY, M.D.

MOUNT VERNON, N. Y.

AND MAURICE LENARSKY, M.D.

Associate Attending Physician and Resident Physician respectively
Willard Parker Hospital

NEW YORK

There are few infectious diseases so frequently incorrectly diagnosed as acute poliomyelitis. In a survey of this disease over a period of four years at the Herman Kiefer Hospital in Detroit, Gordon¹ found that in only half of the 446 patients admitted with a diagnosis of poliomyelitis was the diagnosis confirmed by clinical study and laboratory investigation. Such a finding means that there is need for improvement in diagnostic technique. By studying the mistakes and suggesting when possible, how these mistakes can be avoided, the profession should be able to increase its diagnostic accuracy. With this purpose we record our observations during the epidemic of poliomyelitis in New York in 1931. There were 1,123 patients admitted to the Willard Parker Hospital with a diagnosis of poliomyelitis. After careful examination and observation, poliomyelitis was excluded in 113. These 113 patients form the material for our presentation. This of necessity limits the number of conditions discussed and no attempt will be made to present a complete differential diagnosis of poliomyelitis.

The clinical course of poliomyelitis has been fairly definitely divided into three stages, as shown in the accompanying chart. The first is the period of general invasion, which may last one or two days. During this stage the diagnosis of poliomyelitis is extremely difficult, if not impossible. The patient may complain of headache and malaise and may have some gastrointestinal disturbance and slight fever. Physical examination of the patient often reveals nothing abnormal, or the symptoms and signs may be those frequently found in children with a mild gastro-intestinal upset or a common cold. This stage is frequently either not present or entirely overlooked.

Kramer² has shown that some individuals have developed an immunity as a result of exposure to the disease, even though they showed no symptoms of infection or possibly only the indefinite manifestations of the first stage. He examined the blood of twelve persons who had been in intimate contact with a patient with poliomyelitis. A test for a specific neutralizing substance made a few days following the contact showed all twelve to be nonimmune. Six of the twelve were available for retesting five months later and at that time were found to have become immune. During the five months they had not suffered from any illnesses that could be suspected as being abortive poliomyelitis. That such

cases, whether or not they show clinical symptoms of the first stage of the disease, may be a source of infection was shown by Wickman³ in his classic observations more than twenty-five years ago

In some cases the infectious process continues and localizes in the central nervous system to produce the second or preparalytic stage. There may be an asymptomatic interval of several days between the first and second stages, or the disease may continue without interruption. During the second stage the symptoms are primarily those of meningeal irritation. The patient may be apprehensive, complain of headache and malaise and have fever. Examination may reveal ataxic tremor, stiffness of the spine, resistance to anterior flexion of the head, diminished or absent superficial reflexes, hyperactive, hypo-active or unequal deep reflexes, and sensory disturbances. During this stage, in contrast to the initial period of systemic invasion, the patient exhibits something more tangible on which to base a diagnosis. However, it is important to exclude other diseases in which the central nervous system is primarily or secondarily involved.

The third stage is due to more serious damage in the central nervous system and is evidenced by paralysis or by symptoms of encephalitis. This phase may occur shortly after the first symptoms of meningeal irritation or after an interval of several days.

FIRST STAGE

The first stage of the disease simulates what is generally considered a cold or minor gastro-intestinal upset. Since Wickman first emphasized the importance of what he termed abortive poliomyelitis, various observers⁴ have stated that, during an epidemic, abortive poliomyelitis (those cases not progressing further than the first stage) constitutes as high as from 50 to 80 per cent of the total cases.

From the history or physical signs twenty-eight of our 113 cases could be considered as supposedly falling

Clinical course of poliomyelitis

into the first stage of the disease. There were twenty-eight patients with ten separate conditions in this group, as shown in the accompanying table. Half of the patients had either pharyngitis or gastro-enteritis. There were also two patients with serum reactions, two with evidence of trauma, and one with typhoid. It cannot be

reiterated too often that a careful history and physical examination is important. A history of trauma or recent injection of serum, the finding of an acute follicular tonsillitis or severe pharyngitis explains the con-

dition found in many of the patients. We have observed that in early poliomyelitis the pharyngitis is mild and does not look beefy red or produce an exudate on the tonsils. The gastro-intestinal symptoms that may occur in poliomyelitis are of short duration and are not severe. Examination of the spinal fluid in the first stage of poliomyelitis gives no helpful information. Extreme drowsiness and high fever during the period of systemic invasion have been reported in some epidemics,¹ but we have not encountered such cases.

Gordon¹ has aptly said:

Too often the well appreciated advantages of early diagnosis tend toward overemphasis of poliomyelitis particularly during the period of seasonal prevalence and, if the disease is epidemic with the result that other conditions, of themselves as urgent as poliomyelitis, suffer delay in management because of confusion with that disease. No less stress must be placed on determining poliomyelitis before paralysis, but need does exist for more critical judgment in eliminating allied conditions. The general opinion among physicians that the clinical diagnosis of poliomyelitis has not reached the exactness of other communicable diseases finds ready substantiation.

Some of our children had mild pharyngitis or gastro-enteritis that might have been poliomyelitis. None of these patients gave a history of recent contact with any one with an acute illness. This, of course, does not exclude the possibility of some unrecognized contact. As an additional precaution we kept the children under observation one week after their symptoms subsided to make certain that we were not dealing with a so-called dromedary type of invasion. Because of the two

⁴ Draper, George. Acute Poliomyelitis. Philadelphia: P. Blakiston Co., 1917.

definite masses or humps of symptoms in some cases, the analogy to the arrangement of the dromedary's back was used by Draper¹ to express this type figuratively²

SECOND STAGE

The signs of meningeal irritation which occur during the second or preparalytic stage of poliomyelitis also occur in other diseases. Fifty patients were referred to the hospital supposedly with preparalytic poliomyelitis. Minor illnesses made up almost half of this group. Two cases of tuberculous meningitis were erroneously diagnosed as poliomyelitis in the admitting room. Spinal fluid examination before admission revealed a fluid under slightly increased pressure containing 30 cells, which were mostly mononuclears, slightly increased globulin and a normal amount of sugar. Convalescent poliomyelitis serum had been given intravenously. Tubercle bacilli were later found in the spinal fluid obtained in the hospital, but the sugar content remained normal. This indicates the difficulty in differentiating early tuberculous meningitis from preparalytic poliomyelitis when the sugar content of the spinal fluid remains high. At the time of admission the duration of the meningeal irritation was against the diagnosis of poliomyelitis, but the family physician with the facilities at his disposal was not in a position to make a more accurate diagnosis.

Two cases of pneumonia were incorrectly diagnosed as poliomyelitis on admission. Both were in young children who had meningeal irritation without definite signs in the lungs. The pulmonary signs became evident on subsequent examinations. The spinal fluid in each case was normal, but the blood count showed a greater leukocytosis and a larger percentage of polymorphonuclear cells than were usually found in poliomyelitis. A normal spinal fluid in the presence of meningeal irritation rarely occurs in poliomyelitis. The lesion in one case was a lobar pneumonia of the right upper lobe and in the other a right apical bronchial pneumonia. Two other cases of pneumonia showed definite signs in the lungs at the time of admission.

There were six children with gastro-intestinal symptoms admitted with a diagnosis of preparalytic poliomyelitis. The spinal fluids of all six patients were normal. The gastro-intestinal symptoms occurring at the onset of poliomyelitis are relatively mild, whereas repeated vomiting, frequent bloody, mucoid stools, dehydration or abdominal pain are rare in this disease. When repeated vomiting does occur in poliomyelitis, there is usually a rapid onset of paralysis with bulbar symptoms predominating. It should be noted that slight resistance of the neck to flexion of the head, hyperactive or sluggish deep reflexes may occur in acute gastro-enteritis. In doubtful cases the duration and severity of the symptoms will often help in excluding a diagnosis of poliomyelitis.

The following are illustrative cases of other conditions that were encountered.

One child was admitted with a history of vomiting, headache, drowsiness and epistaxis. The temperature was 104 F and the pharynx was red. Examination at the time of admission revealed slight stiffness of the neck, a nasal twang to the voice and irregularity in the patellar reflexes. The spinal fluid was normal. After further observation a diagnosis of grip was made.

This case again points out that a child with a high temperature may have slight nuchal resistance and, when differences in reflexes are slight, they should be carefully reexamined. The nasal twang to the voice was apparently due to the child's drowsiness.

A boy, aged 12 years, was admitted with a history of pain in the shoulders and neck. There was no fever. The patellar reflexes were hyperactive. Examination revealed that the muscles in the back of the neck were tender. There was pain on extreme flexion of the head. The spinal fluid was normal. The myositis gradually subsided and the patient was discharged after six days.

There were five patients in whom it was difficult to exclude poliomyelitis with certainty.

One child, aged 8 years, was admitted with a history of fever, headache, malaise, pain in the neck and legs for one day and constipation for two days. The temperature was 103.8 F. Neurologic examination in the hospital was negative. Following catharsis the temperature remained normal after the second day in the hospital. The spinal fluid was normal.

Another child, aged 6 years, was admitted with a history of fever, headache and pain in the back of the neck. The child was acutely ill, with a temperature of 103 F, the tonsils were enlarged and reddened, the patellar reflexes were hyperactive and there was slight nuchal resistance. The following day the temperature was normal and all symptoms were gone.

Another child, aged 4 years, whose brother had been under observation for poliomyelitis at the hospital for four days three weeks before, was admitted with a history of fever, vomiting and pain in the back and neck. The child was acutely ill, with a temperature of 104 F, and there was slight resistance on extreme flexion of the head. The following day the temperature was normal. The spinal fluid was normal.

Two other children presented similar pictures. These children were all acutely ill for a day or two, there were no, or only slightly abnormal, neurologic signs, and other symptoms were those of pharyngitis or tonsillitis. They were kept under observation to exclude the possibility that we were dealing with the dromedary type of invasion. The children were well when discharged with a diagnosis of "not poliomyelitis." It seems that some of the children were more ill than those usually exhibiting the early symptoms of poliomyelitis as we have seen them. Severe symptoms at the onset of poliomyelitis are associated with a virulent infection and are usually followed by definite symptoms of invasion of the central nervous system. We felt that, even if our patients had had either abortive or preparalytic poliomyelitis, there was little chance of their spreading the disease after their discharge. Since then Paul, Salinger and Trask³ have examined the nasopharyngeal washings of children who had minor illnesses (similar to abortive poliomyelitis) in a small community in which poliomyelitis had occurred. The washings from twelve children were examined at different stages of their illness. Virus was demonstrated in two cases in which the washings were taken within forty-eight hours after the onset of the illness. This suggests that the period of contagion is of short duration.

THIRD STAGE

Twenty conditions occurred in the third group of patients admitted with a history or symptoms suggesting the third or paralytic stage of poliomyelitis. Two children with gastro-enteritis and one with pharyngitis each had a history of weakness of the legs. Three

¹ Stimson has recently pointed out that this term is descriptively inaccurate. A dromedary (Arabian camel) has but one hump; it is the Bactrian camel that has two. (Stimson P. M. Common Contagious Diseases. Philadelphia: Lea & Febiger, 1931.)

² Paul, J. R., Salinger, Robert and Trask, J. D. Abortive Poliomyelitis. J. A. M. A. 98: 2262 (June 25) 1932.

patients with obvious injuries were brought to the hospital because they could not move one of the extremities. Two children refused to move their legs because they had osteomyelitis. Swelling and constant marked localized tenderness do not occur in poliomyelitis. One adult had taken huge doses of some hypnotic and a multiple neuritis had developed. A child aged 4 years, refused to move his arm because he had cellulitis of the chest wall with axillary adenitis. Three patients with pneumonia were admitted in respiratory distress and two of these had a history of weakness of the legs and stiffness of the neck. At the time of admission there were definite signs of pneumonia with difficulty in the expiratory phase of respiration. In the respiratory paralysis of poliomyelitis the respiratory difficulty is in inspiration. Cough is an infrequent symptom in poliomyelitis. Several elderly patients with cerebral accidents were admitted to the hospital and in each instance the diagnosis was obvious.

The following are brief outlines of some of the more instructive cases.

A boy, aged 8 years, was admitted with a history of convulsions, cyanosis, generalized rigidity and fever. He had ptosis of the right upper lid. The patient presented the characteristic symptoms of tetanus and recovered after appropriate treatment.

We did not observe convulsions and generalized muscular rigidity in any of our cases in 1931. However, in 1933 convulsions and muscular spasticity occurred in a child, aged 17 months, who had a bulbo-cerebral lesion. Patients with respiratory failure sometimes have convulsive seizures (probably asphyxial) a short time before death.

A child, aged 12 years, was admitted with a history of anorexia, diarrhea, backache, irritability and paralysis of the left lower extremity. Careful examination revealed involvement of the left hip joint. Roentgenograms and tuberculin tests were negative. The child was transferred to an orthopedic hospital with a diagnosis of early epiphysitis or synovitis.

Another child, aged 15 months, was admitted with a history of irritability, vomiting, fever, weakness of the legs and pain in the right arm. There was swelling and bluish discoloration of the skin around the right elbow joint. The lower extremities were normal. The child was transferred to Bellevue Hospital, where pus was aspirated from the joint.

Poliomyelitis should have been readily excluded in each case. Limitation of passive motion, if it occurs at all, is minimal in poliomyelitis, and swelling does not occur.

A well developed girl, aged 16 years, was admitted with a history of convulsions and coma. The diagnosis at the time of admission was not clear and she was admitted for observation. The following day there was a complete right flaccid hemiplegia due apparently to a localized cerebral lesion. The patient lingered in semicomatose for two days and then died. A large cerebral hemorrhage was found at autopsy.

When a case of meningococcic meningitis is considered to be poliomyelitis it is a serious error in diagnosis. The longer the delay in administering specific serum to a patient with meningococcic meningitis the less favorable the prognosis. This is particularly true in infants who, unfortunately, present the most difficulties in diagnosis. The following cases are illustrative.

An infant, aged 15 months, was sent to us from another hospital with a history of fever of several days duration and of inability to stand on the right leg. The cell count in the spinal fluid was reported as 50. On admission the infant had

a temperature of 104 F, stiff back and slight fulness of the fontanel. The spinal fluid was under increased pressure, there was no sugar, a slight increase in globulin and 660 cells, most of which were polymorphonuclears. Gram-negative cocci were found on direct smear. The child recovered following appropriate treatment.

There should have been less doubt about the diagnosis in another child, aged 4½ years, even though there was a right facial paresis and absent patellar and achilles reflexes. The child was toxic, the temperature was 104 F, and bilateral Brudzinski and Babinski reflexes, stiff neck, and a petechial rash were present. The spinal fluid was under increased pressure and cloudy, with a marked increase in globulin and no sugar. Meningococci grew on culture. The child recovered.

Isolated paresis and absent deep reflexes may occur in cerebrospinal meningitis. The presence of a petechial rash and signs of meningitis in an acutely ill, toxic child should leave little doubt as to the proper diagnosis, even before the spinal fluid is examined.

A girl, aged 18 years, had fainted a week before and then was unable to move her arms and legs. Three days later she was able to move her left arm and leg. At the time of admission the temperature was normal and there were no signs of meningeal irritation. She could not stand because of severe pain in the muscles of the right leg. There was marked dermatographia. The grip of the left hand was weak. Movements of the right foot were sluggish. All deep reflexes were diminished. There was hyperesthesia over the entire right leg and an area of hypesthesia on the sole of the right foot. The spinal fluid was normal. A neurologic consultant stated that she had an emotional disturbance (stepfather difficulty and new position for three days). The diagnosis was hysteria.

An infant, aged 8 months, was admitted after an illness of two days, which started with fever, vomiting and paralysis of the left leg. At the time of admission the temperature was 100 F and the respiration rate 30. The infant did not move the left leg but all deep reflexes were active. The spinal fluid was normal. The blood count showed 16,000 leukocytes with 73 per cent polymorphonuclears. The following day the temperature rose to 103 F. A roentgenogram of the hip was negative. The spinal fluid twenty-four hours after admission showed 50 cells, mostly polymorphonuclears, increased globulin and decreased sugar. Blood culture was negative. The temperature continued to rise. Signs of meningeal irritation developed and the child died thirty-six hours after admission. Autopsy revealed a purulent arthritis of the hip and early meningitis.

A white girl, aged 18 years, was admitted with a history of pain in the lumbar region of the back and weakness and numbness of the left leg of two days duration. At the time of admission the temperature was 100 F. There was decreased muscle power in the entire left lower extremity and diminished sensation to touch. The knee jerk was hyperactive and the abdominal reflexes were diminished on the left side. A roentgenogram of the spine was negative. A blood count revealed 5,100,000 red cells, hemoglobin 75 per cent, white cells 10,350 with 76 per cent polymorphonuclears. Chemical examination of the spinal fluid gave negative results and there were 8 mononuclears per cubic millimeter. Dr. Burchell in neurologic consultation made a diagnosis of focal myelitis on the left side of the cord at the second lumbar segment. She gradually improved and was discharged after nine days.

A white youth, aged 20, had a boil on the cheek a week before admission. Three days later he had a fever and complained of pain in the lumbar region of the back. He was treated for lumbago. The day before admission paralysis of the legs developed. At the time of admission he was acutely ill, the neck and back were stiff and deep reflexes of the lower extremities as well as the abdominal and cremasteric reflexes were absent. Accurate sensory determinations could not be made but there was apparently no response to pain or touch in the lower extremities. The bladder was distended. The temperature was 103.2 F. Ten cubic centimeters of yellow

tinged fluid under slightly increased pressure was obtained by lumbar puncture. The sugar content was normal, the albumin and globulin were greatly increased and the cell count was 4 mononuclears. Culture of the fluid showed no growth. A blood count revealed red blood cells, 3,620,000, hemoglobin 75 per cent, white blood cells 21,800 with 84 per cent polymorphonuclears. He soon became stuporous. On the second day in the hospital his breathing became rapid and there were signs of pulmonary infiltration. A roentgenogram showed the vertebrae to be normal. Blood taken on the fourth day in the hospital yielded staphylococci on culture. The temperature remained between 104 F and 106 F. There was retention of urine and feces. The patient became worse and died five days after admission. The autopsy revealed multiple abscesses of the lungs and epidural abscesses about the cord.

COMMENT

As in other diseases the greatest difficulty in making a diagnosis in poliomyelitis is to make it early in its course. During the first stage the period of systemic invasion, the greatest problem is presented by mild infections of the upper respiratory tract and gastrointestinal upsets. These are encountered more frequently in private practice than in hospital practice, especially during an epidemic, when parents are apprehensive about any abnormal symptoms that their children may manifest. Infections of the upper respiratory tract and intestinal upsets occur at times when poliomyelitis is not prevalent, and it is well to remember that even during an epidemic not all minor illnesses are necessarily poliomyelitis.

Careful observers studying this problem have given conflicting opinions. Paul, Salinger and Trask⁹ give circumstantial evidence with some experimental support to the relation of characteristic minor illnesses to poliomyelitis. They consider characteristic minor illnesses those in which there is an acute febrile episode with sore throat, headache and vomiting, which lasts from twenty-four to thirty-six hours, as a rule leaving the patient feeling below par for several days. Three separate counties in which poliomyelitis occurred were closely observed for the occurrence of minor illnesses. In all three the ratio of cases of poliomyelitis to minor illnesses was approximately the same, namely 1:6. Among 450 children from families in which a case of poliomyelitis occurred the incidence of minor illnesses was about 24 per cent, whereas among 266 children from families free of poliomyelitis the incidence of minor illnesses was only about 7 per cent. Washings from the nasopharynx of twelve children with characteristic minor illnesses were tested for the presence of virus by intracerebral inoculation of monkeys. The presence of virus was demonstrated in two children from whom the washings were taken within forty-eight hours of the onset of their illness.

On the other hand, Kramer reports the following:

A recent survey in a small town in which five cases of poliomyelitis occurred revealed thirty-three cases of mild illness in children with such symptoms as headache, fever and vomiting without apparent cause. In proximity to frank cases these illnesses could have been abortive poliomyelitis. Tests for a neutralizing substance were made on these children several months after the illness and it was found that the number who were immune was no greater than in a group of children of the same age in the same town who had had no illness. A like number of children of the same ages from an adjacent town which had been free from poliomyelitis showed the same proportion of immunity. These results indicate that the children who were ill did not suffer from poliomyelitis or in any event that the infection did not confer immunity to the disease.

Studies of the immune reaction of two other groups of contacts showed that immunity results only when there has been intimate contact with the patient. Moreover, immunity may follow exposure to the virus without evidence of any disease.

Such conflicting opinions leave the clinician in a quandary. The only suggestions that we can give from our experience with the first stage of the disease are of a negative nature. We have not observed poliomyelitis begin with severe persistent diarrhea, purulent otitis media, follicular tonsillitis or diffuse tonsillitis with membrane formation, such as is seen in streptococcal infections.

When poliomyelitis progresses beyond the first stage, the infectious process localizes in the central nervous system and causes signs of meningeal irritation. There are many conditions in childhood unrelated to disease of the nervous system which may be associated with symptoms of meningeal irritation. A careful history and physical examination is of great importance. A stiff neck associated with an inflamed middle ear, pneumonia, severe pharyngitis, tonsillitis or persistent diarrhea is probably not due to poliomyelitis. Retropharyngeal abscess or myositis of the neck muscles may cause nuchal resistance. The diagnosis of the various types of meningitis can at times be made only by lumbar puncture. In patients with meningococcal meningitis it is of especial importance to make the correct diagnosis early. The spinal fluid during the second stage of poliomyelitis usually shows some abnormalities but it may be normal. Among several thousand lumbar punctures over a period of years we have occasionally encountered turbid fluid in poliomyelitis. One patient had 1,500 cells, but the majority have less than 300 cells. The polymorphonuclear percentage is occasionally high. The sugar content is usually normal, rarely low and never absent. In our laboratories no organisms have been found in cultures from the spinal fluid of patients with poliomyelitis. Spinal fluids from some cases of tuberculous meningitis and of syphilis of the central nervous system simulate those from poliomyelitis. Colloidal gold tests, serologic and bacteriologic examinations, and the Mantoux skin test will help clarify the situation. Other stigmas of congenital syphilis may be present. An additional helpful point is that the onset in tuberculosis or syphilis of the central nervous system is less acute than in poliomyelitis.

Further advance of the infectious process in poliomyelitis produces signs of paralysis or encephalitis. Paralysis may be simulated by abnormal conditions in the muscles, bones or joints. This occurred in eleven of our patients. Age is an important factor in making the diagnosis of poliomyelitis in the paralytic stage. Cerebral hemorrhage and arteriosclerosis are not uncommon in persons over 50 years of age, whereas poliomyelitis is rare in that period of life. One unusual case cited in the text was that of a cerebral hemorrhage in a girl, aged 16 years. In infants, scurvy and syphilitic pseudoparalysis may simulate poliomyelitis. In scurvy, muscle tenderness is greater, and the thigh, which is the part most frequently involved, is held in flexion. Hemorrhage into the gums or muscles and lowered resistance of the capillaries of the skin⁷ aid in the diagnosis. In syphilitic pseudoparalysis there may be swelling over the affected epiphysis and crepitus may be elicited. There is usually marked tenderness on

⁷ Dalldorf, Gilbert. A Sensitive Test for Subclinical Scurvy in Man. *Am. J. Dis. Child.* 46: 794 (Oct.) 1933.

passive motion. Examination for other stigmata of syphilis, as well as a history and a Wassermann reaction, is of obvious importance.

The cell count of the spinal fluid in poliomyelitis is usually increased if the paralysis is seen early. On a few occasions we have encountered a cell count within normal limits. When lumbar puncture is done after the paralysis has been present for some time, the spinal fluid is frequently normal. Usually the changes in the spinal fluid during the first days of paralysis are similar to those which occur during the period of meningeal irritation (second stage), already described.

Several patients with pneumonia were sent to the hospital with the diagnosis of respiratory failure due to poliomyelitis. The respiratory difficulty in pneumonia is expiratory, in poliomyelitis it is inspiratory. There is almost always paralysis of other muscles in addition to the respiratory muscles in patients with poliomyelitis. Cough does not occur in poliomyelitis except possibly from irritation of retropharyngeal saliva in those patients who cannot swallow. Physical signs are present when a patient has marked respiratory difficulty due to pneumonia. Only occasionally does pneumonia complicate the respiratory paralysis early in its course. Among forty-five patients treated in the respirators at the Willard Parker Hospital in 1931, one had signs of pneumonia two days after the respiratory difficulty began.⁸

SUMMARY

There were 1,123 patients admitted to the Willard Parker Hospital in 1931 with the diagnosis of poliomyelitis. Among these there were 113 who did not have poliomyelitis but in whom thirty-six other conditions were diagnosed after clinical study and laboratory investigation in the hospital. There were twenty-eight patients with ten different conditions who supposedly had poliomyelitis in the first stage, fifty patients with twenty different conditions simulating poliomyelitis in the second stage, and thirty-five patients with twenty-one different conditions simulating poliomyelitis in the third stage.

The majority of these patients should have had a correct diagnosis made by their personal physician, even though the diagnostic difficulties are greater in the home than in the hospital. The family physician sees many patients in the first stage of the disease, at a time when he is unable, with certainty to establish the diagnosis of poliomyelitis. However, in many instances it is possible to find some other condition to account for the patient's symptoms. There is a tendency, especially during epidemic periods, to make the diagnosis of poliomyelitis without obtaining a history and making a careful physical examination. As the disease progresses into the second or third stage there are more tangible symptoms on which to make a positive diagnosis of poliomyelitis. Parallel with the increase in the number of symptoms there is an increase in the number of conditions mistaken for poliomyelitis.

Nothing is more important than a careful history and physical examination. If, in addition, poliomyelitis is considered as occurring in three stages, the differential diagnosis will be simpler and the percentage of incorrect diagnoses will decrease. To this end, the experience and information from our series of hospitalized patients is presented.

TREATMENT OF ACUTE PULMONARY ABSCESS

S U MARIETTA, M D
WASHINGTON, D C

This discussion will have to do with single (including multilocular) abscesses and does not include those due to tuberculosis, bronchiectasis and new growths. The subject has been frequently discussed in medical literature, but in my opinion the difference in treatment to be directed to the acute in contradistinction to the chronic process has not been sufficiently stressed. The importance of postural drainage in the treatment of the acute condition has received little more than casual mention.

Although the treatment of acute lung abscess is relatively simple, it is apparently unfamiliar to the very class of physicians who should be able to apply it early and to carry it to a successful conclusion in more than 50 per cent of the cases, i. e., the general practitioner. Many patients with chronic pulmonary abscess who are seen have never received any treatment during the acute stage other than rest in bed "cough medicine" and perhaps forced feeding of milk and eggs, following the procedure in vogue for pulmonary tuberculosis years ago.

GENERAL CONSIDERATIONS

In this paper, in order to emphasize the purely "medical" treatment bronchoscopy will be considered as surgical treatment, also, artificial pneumothorax, will be classed as surgical along with phrenicectomy, incision and drainage, thoracoplasty and lobectomy.

The treatment of all acute cases of pulmonary abscess is medical until it becomes evident that such treatment will not succeed. The period to be covered by the medical treatment varies from six to twelve weeks in the opinion of different writers, but in general it may be said that the time element alone is not the important factor. The location of the abscess and especially the development of a heavy, more or less rigid, cavity wall, which will not permit of the closure of the cavity through the natural elasticity of the pulmonary parenchyma, are better guides as to when surgical intervention may be indicated. On the other hand, continuous, perhaps rapid, extension of the area of suppurative pneumonia surrounding the abscess cavity, with concomitant enlargement of the cavity and possibly the appearance of other cavities in the contiguous pneumonia area, indicates the failure of medical treatment alone.

The general condition of the patient and his willingness to cooperate must also be given consideration in selecting the time for surgical intervention.

If continuous improvement takes place, as evidenced by gradual lowering of the temperature to normal, decrease in the amount and offensiveness of the sputum, decrease in the white blood count, improvement in the appetite and the general condition, less cough, with a cleaning up of the involved area as shown by roentgenograms and physical examination, the probabilities of healing by medical treatment alone are good. However, even if the improvement is not steady, medical treatment should be continued for a reasonable period if there is not a definitely downward trend. The site of the abscess cavity must also receive consideration.

because, as Fischel² has noted, collapsibility increases with the distance from the pleura. A cavity that is some distance from the pleura can be collapsed, provided the walls are not already fibrosed and thickened too much, because it is surrounded on all sides by elastic pulmonary parenchyma. When the cavity is so near to the overlying pleura that the visceral and parietal layers have become adherent, elimination of the cavity by contraction becomes difficult and perhaps impossible.

Fig 1—Single chronic abscess, right lower lobe. Thick fibrous rigid cavity wall and absence of contiguous pneumonitis. There was little or no cough and scanty expectoration. The temperature and white blood count were normal and there were few physical manifestations.

Such cases may be decided, while still in the acute stage, to be proper ones for incision and drainage (figs 2, 3 and 4).

In general avoidance of surgery if possible is indicated. With such surgical procedures as incision and drainage, or thoracoplasty, there is always a certain amount of deformity and with the former a variable amount of scar tissue, which may encourage the later development of bronchiectasis, also.

Cherry³ considers as further drawbacks the possibility of hemorrhage and failure to eradicate the abscess, as well as ankyloid changes in the important organs, which may occur with a protracted recovery. Unfortunately, a number of surgeons hold with Connors⁴ the view that few abscesses are cured by medical means, even with the assistance of the bronchoscope. This attitude on the part of surgical consultants is productive of unnecessary surgical procedures with results inferior in many cases to those which should be obtained by proper medical treatment. It is doubtful even whether the course of the disease is shortened greatly by surgical procedure, as a considerable period of convalescence is necessary following either medical or surgical treatment to prevent recurrence of the abscess.

ETIOLOGIC FACTORS

The etiologic factors in pulmonary abscess have directly to do at times with the form of treatment to be undertaken. Smith⁵ states that 90 per cent of the cases of pulmonary abscess in adults are caused by the fusospirochetal organisms (fusiform bacilli, spirochetes, vibrios and cocci) which are commonly found in pyorrhea and Vincent's angina. He says that laboratory studies support clinical observation to the effect that the diseased mouth is a source of infection. Early treatment with arsenical preparations will, he finds, control this type of lesion, often in the initial stage of pneumonitis. That aspiration from a foul mouth may be a prolific cause of lung abscess seems plausible, but I

do not believe that this type of organism is generally found in so high a proportion of cases. I always have the sputum of patients examined for spirochetes but have found only a small proportion positive. The sputum, however, was collected in a sterile petri dish and was that produced from the lung after coughing, the mouth having been thoroughly washed out previously.

Harrington,⁶ Clerf⁷ and Frank⁸ mention as important etiologic factors streptococcal bronchopneumonia (rarely pneumococcal pneumonia), aspiration of a foreign body or of septic material from operative procedures on the upper respiratory tract, and septic emboli following any operative procedure. Frank's discussion of the question as to whether postoperative lung abscess results from embolism due to the dislodgment of an infected thrombus from vessels in the operative area rather than from aspiration of infected material indicates that writers in general favor aspiration instead of embolism, four to one.

SYMPTOMS

The symptoms of pulmonary abscess are not diagnostic early. The generally acute onset, the largely unproductive cough, perhaps dyspnea, elevation of temperature, pain in the chest if there is pleural involvement, sweating, chills or chilly sensations and polymorphonuclear leukocytosis might be due to any one of several pathologic processes, such as lobar or lobular pneumonia, or pneumonitis around an old bronchiectatic area. The onset may be more gradual with general malaise, moderate fever, unproductive cough and a gradually increasing leukocyte count. The physical signs at this stage are not diagnostic and roentgenograms, though they show the location of the pathologic changes, contain nothing distinctive or characteristic of abscess. The characteristic sign of a fully developed abscess is the sudden expectoration of a large amount of more or less offensive pus. Later the sputum is offensive, largely in proportion to the amount of gangrene, which in turn depends on the type of infection present. The separation of the sputum in three layers, mentioned in many textbooks as distinctive of bronchiectasis, is of little or no value. The amount of expectoration, except at the time of rupture of the abscess into a bronchus, is not a positive indication of the size of the abscess or of the degree of drainage. Fever is present in the acute abscess but often absent in the old chronic case.

with good drainage however, the height and persistence of the temperature is in direct relation to the freedom of the drainage. Chills and sweats are more common when gangrene is present.

DIAGNOSIS

The diagnosis is one of elimination. A history of any of the etiologic factors mentioned is of great importance. Physical examinations and roentgenograms are of great

Fig 3—Same case as in figure 2 eleven days later. Cavity enlarging rapidly in spite of good drainage by posture.

The injection of iodized poppy-seed oil for the localization of the abscess cavity may at times be necessary, but I have found it so only exceptionally. The use of the bronchoscope as a means of diagnosis is a matter of opinion. Such formerly recommended procedures as exploratory chest punctures need be mentioned only to be condemned.

The differential diagnosis must take into consideration bronchiectasis, gangrene, encysted empyema, pulmonary tuberculosis and pneumonia.

PROGNOSIS

The prognosis of pulmonary abscess depends on its etiology, its location, the length of time the patient can afford to give to treatment, the period during which he can give proper care to himself after treatment is completed, and the general condition of the patient and the occurrence and type of complications. At times postural drainage or bronchoscopy or both have to be discontinued because of hemoptysis.

Harrington⁶ believes that more than 50 per cent of cases respond to conservative measures. Clerf⁷ reports fifty-eight cases, twenty-four of which were treated by bronchoscopy, of the twenty-four patients 79 per cent were discharged as well. Miller⁸ quotes Lord as estimating the mortality of medically treated abscesses as 75 per cent, but he himself agrees with Glowacki that 50 per cent of the patients will recover under rest, posture and bronchoscopy. Tewksbury reported a 60 per cent mortality and Greer 30 per cent in cases in which only medical treatment was given. Whitmore has considered from 10 to 30 per cent of cases curable by expectant treatment if it is instituted early. It has been stated that the percentage of recovery under medical treatment is greater in upper lobe cases. None of the

writers mentioned have made any mention as to whether their cases were of the acute or the chronic variety.

The mortality rate given by different authors, therefore, varies widely for medically treated cases. This would indicate that the method of carrying out the treatment must be at somewhat equal variance, although the number of cases reported, as well as their individual differences, would account for some of the discrepancy. However, as the best treatment consistently applied should approximate the best results, the treatment in some instances would seem to have been substandard.

ACUTE VERSUS CHRONIC ABSCESS

Before treatment is considered in detail it is advisable to specify what is meant by acute and by chronic lung abscess. Acute abscess may be defined as an area of destructive pneumonitis or necrosis without definite walling off or fibrosed limitation and surrounded by a more or less extensive acute pneumonitis, these being the sequelae of any of the etiologic factors mentioned previously, the process not being due to tuberculosis, new growth and, for the purpose of this discussion, bronchiectasis.

There has always been a clinical differentiation between those areas of pneumonitis which may or may not be the precursors of a lung abscess and the actually developed abscesses in which there is breaking down of lung tissue within an area of preexisting pneumonitis. This may not be of any special significance, however, it is evident that the results in the treatment of a pneumonitis, which goes on to resolution without breaking down, and actual formation of an abscess will yield a considerably higher percentage of cures or recoveries than the latter. When an abscess wall develops and the surrounding pathologic process assumes a stationary and dense appearance on the roentgenogram, indicating the presence of considerable fibrosis, and the patient's symptoms subside, the chronic stage has been reached (fig 1).³

TREATMENT OF ABSCESS

In chronic abscess medical treatment is of use for only a relatively short period to improve the general condition of the patient before proceeding

to the selected surgical procedure. In other words the elimination of a chronic lung abscess by medical treatment alone is not to be expected as the inelastic fibrous wall present in this condition will not permit closure of the cavity, although it may be kept empty by postural drainage and the general condition of the patient may be improved thereby. Medical treatment for a period before surgery will often clear up an area of suppurative pneumonitis contiguous to the cavity, thereby tending to lower postoperative mortality. Medical

Fig 4—Appearance eighteen days after figure 3. Injection and drainage with packing with excellent result.

⁶ Miller, John. A Review of One Hundred Cases of Abscess of the Lung. *Ann. Otol. Rhin. & Laryng.* 40: 1195-1211 (Dec) 1931.

treatment postoperatively, especially following such procedures as artificial pneumothorax, phrenicectomy or thoracoplasty will often expedite and render more probable a satisfactory result.

The medical treatment of an acute abscess has been mentioned in more or less detail by various writers.¹⁰ At the first suspicion of an abscess the patient should be placed at rest in bed and should remain there until the temperature has been normal for one month. During the early stage, i. e. prior to the rupture of the abscess into a bronchus, treatment should be that of an acute respiratory infection and be expectant through the more or less long drawn out period which the patient will pass through subsequent to rupture of the abscess. Free fluid intake should be insisted on, he should be given a high calory and high vitamin diet, and proper elimination should be provided. He should not be allowed to lose an undue amount of rest at night because of a harassing cough. There is very little expectoration prior to rupture and sedatives should be used cautiously as it is not desirable to destroy the cough reflex.

In all but a small number of cases the abscess will rupture into a bronchus in from a few days to two weeks, and drainage is established. In a case in which rupture does not take place and destruction of lung tissue is progressive, some surgical procedure will be indicated. As soon as the abscess ruptures there will be a considerable amount of foul pus coughed up. As soon as possible a smear and culture should be made of the sputum to determine the types of the prevalent organisms, and especially the presence of spirochetes, and postural drainage should be started at once. If spirochetes are present, two or three small doses (0.3 Gm.) of arsphenamine should be given.

By postural drainage is meant the mechanical emptying of the abscess area as far as possible by placing the patient in such positions as will best bring this about. In lung abscess as in any localized suppurative process the primary desideratum is drainage, and the progress toward improvement, recovery or cure will depend on the degree of drainage. The frequency with which the postural drainage is done and the length of time spent on each drainage will depend on such factors as the size of the bronchus draining the abscess area, the viscosity of the sputum, the tendency toward hemorrhage and the general condition of the patient. The drainage itself is performed by first placing the patient for five or ten minutes on the healthy side, this is to permit the purulent material to drain down into the larger bronchi so that the next step, the inversion of the patient will be more productive of further drainage. If the abscess is in an upper lobe, it is well to have the patient sit erect for five or ten minutes before taking the position of lying on the healthy side. The inversion of the patient is best performed by having the patient lie across the bed, face down, with the groins at the edge of the bed so that as the body is bent at the hips the head is at or near the floor, with the body vertical. The weight may be partially supported by the hands at the sides of the head, and further assistance

is given by having an attendant hold the thighs as they lie across the bed. A pus basin is placed on the floor by the head for the collection of the sputum. The inverted position should be held for at least three to five minutes, and if the drainage is slow or is better promoted by a longer period it should last for ten minutes. Most patients do not find this too difficult after they become somewhat accustomed to it. Ordinarily this procedure of drainage, including the lying on the healthy side and the inversion, should be done four times in the twenty-four hours, one half hour before each meal and at bedtime. However, if the abscess area is not clearing up satisfactorily, the drainage can be done more frequently. When progress is slow it is perhaps better to drain more frequently and for shorter periods, say at two and one half hour intervals six times a day. It is to be borne in mind that the patient and not the disease is the first consideration as to the frequency and duration of postural drainage. Further, it is not to be expected that the purulent sputum will all drain out of the patient during the period in which he is inverted as if he were a bottle. The purulent material, however, will be carried down into the bronchi by the drainage, so that the cough reflex later will bring about its removal, and it is in the period following the drainage that the patient raises most of the sputum, hence the necessity for not giving sedatives to the extent of destroying the cough reflex in the treatment of lung abscess.

The Jacksons¹⁰ emphasize the importance of the 'tussive squeeze' in natural peroral drainage and emphasize the deleterious action of codeine on a patient trying to cough up pus. They state that the cough reflex is the "watch dog of the lungs" and that the indiscriminate giving of sedatives to lessen the cough reflex is logically unsound and clinically pernicious, opium derivatives being especially bad in that they not only check the cough but thicken the pus by checking the normal secretions that should thin it, this is of great importance, because the tendency too often is to give opiates of some variety to "keep down the cough."

Failure in the postural method of treatment generally occurs as the result of the patient not being placed in the position best calculated to assist drainage and not using it frequently enough or for long enough periods. This drainage is not a matter that can be left to the patient, it must be supervised and the patient encouraged in its use.

Several appliances, especially various tables of the swivel type, have been advocated for use in bringing about this drainage. None of them, in my opinion, have any advantage over the use of the patient's bed except the financial advantage derived by the manufacturer. Most of them do not permit placing the patient in the completely inverted position, which is desirable as the terminal part of the procedure. Furthermore, they require the patient to be moved to them, sometimes for a considerable distance, and make an annoying and time-consuming matter out of what should be a perfectly simple procedure.

When the sputum is viscid and difficulty is experienced in getting drainage, the judicious administration of expectorant cough mixtures such as potassium iodide or ammonium chloride will be of assistance. Bronchocopy is particularly indicated if drainage is still obstructed by thick inspissated secretion, granulation tissue inflammatory exudate or massive necrotic tissue blocking the draining bronchus. Clerf¹¹ feels that

bronchoscopy shortens the course of the disease in those patients who would have gotten well without it

* For short periods when the sputum is foul and offensive to the patient I have used small doses of creosote with benefit. Frequent cleansing of the mouth with pungent mouth washes also is comforting to the patient.

Postural drainage must be persisted in, even if at times there seems to be little in the way of results at the time of drainage, and, even after the abscess area

has largely cleared up as shown by physical and roentgen examinations, drainage should be continued in order to prevent the accumulation of secretions and a recurrence of the abscess. I keep patients in bed for one month after the temperature is normal and take another month in getting them up, with another month of convalescence, during all of which postural drainage is continued, although not as strenuously as during the acute stage.

Fig 5—Single acute abscess right upper lobe. (In this woman the breasts hanging low give a false impression of a pneumonitis at each base.) At the time this plate was taken she had been under treatment for two months but had not had postural drainage.

It has seemed to me that the *sine qua non* in treatment is drainage. Emetine (Pinchin and Morlock¹⁰) has been recommended but I have used it only in one case in which the abscess was the result of extension from an amebic abscess of the liver. The statement has been made (Young¹⁰) that the percentage of recovery is greater in cases of upper lobe abscess. This is possibly true, but postural drainage is still required, as evidenced by a case shown in figures 5 and 6. The treatment of the foreign body abscess is, of course, bronchoscopic, with removal of the foreign body, following which postural drainage will generally clear up the abscess without difficulty. Although I have classified artificial pneumothorax here as a surgical procedure in order to define more sharply the results that may be obtained by medical treatment alone, I have always carried out artificial pneumothorax in the medical service. Artificial pneumothorax is indicated only in centrally located abscesses when there are no pleural adhesions and the abscesses are favorably situated for drainage through a bronchus. Only a small percentage of cases are suitable for this procedure which is contraindicated in the peripheral abscess because of adhesions which prevent collapse or, by pulling on the abscess wall, cause tearing with rupture of the abscess into the pleural cavity and resulting empyema, a most serious and frequently fatal complication. Jump and Baumann¹⁰ feel that artificial pneumothorax is actually contraindicated, as drainage and not rest and collapse of the lung is desired.

Fischel² feels that pneumothorax generally results in useless collapse because the compression affects the healthy portions of the lung, the cavities remaining patent. This would hardly apply as an objection in the

case of acute abscess in which there is no resistant cavity wall.

Removal of marked foci of infection about the mouth, such as pus pockets about the teeth or draining alveolar abscesses, as well as the cleaning of insanitary teeth, is a part of the treatment as well as a prophylaxis of lung abscess and should be attended to as soon as the patient is seen, unless his physical condition is such as definitely to contraindicate it.

Vaccines, stock or autogenous, are of no benefit in the treatment of acute cases and probably have little promise in chronic cases.

REPORT OF FIFTY CASES

The opinions expressed on the treatment of acute pulmonary abscess are emphasized by the experience gained in a series of fifty consecutive cases seen by me in the past ten years. During this period the acute cases have approximated 50 per cent of the abscess cases seen, perhaps a little less but no complete records were kept of the chronic cases. Only completed cases are considered, those remaining in the hospital not being included.

The ages of the patients varied from 19 to 61 years.

The location of the abscesses was as follows: right upper lobe, thirteen (26 per cent), right lower lobe, fifteen (30 per cent), right middle lobe, two (4 per cent), left upper lobe, six (12 per cent), left lower lobe, fourteen (28 per cent). Forty-six of the cases, or 92 per cent, were single abscesses and four, or 8 per cent, were multilocular.

The etiologic factors were: pneumonia (based on the history with the type undetermined) seventeen (34 per cent) (only two of these cases occurred following pneumonia in my own wards), following extraction of teeth (local anesthetic), two (4 per cent), following tonsillectomy (local anesthetic), one (2 per cent), extension of amebic liver abscess, one, following operation on the mandible, one, following grip, one, chest trauma and aspiration of fluid (automobile accident in which the car turned over and the patient was held under water for a few moments) one, peritonsillar abscess with rupture and aspiration of purulent material one, foreign body (dental bridge—two tooth) one, undetermined (but many with foul dental conditions) twenty-four (48 per cent).

The types of organism found were as follows: streptococci seven (14 per cent), pneumococci six (12 per cent), mixed streptococci and staphylococci twenty (40 per cent), undetermined seventeen (34 per cent).

Surgical treatment was required in the following cases: bronchoscopy (one in aspirated dental bridge) three (6 per cent), artificial pneumothorax, six (12

Fig 6—Same case as in figure 5. Appeared fifteen days after the beginning of postural drainage. This illustrates the necessity for postural drainage even in upper lobe abscesses and shows its efficacy.

per cent), phrenicectomy (one case crushing only), two (4 per cent), incision and drainage, six (12 per cent), thoracoplasty, two (4 per cent)

The complications noted were purulent pericarditis, one (2 per cent), spontaneous pneumothorax (following artificial pneumothorax), one, empyema with bronchopulmonary fistula, one, closed empyema, two (4 per cent), brain abscess, one, aspiration bronchopneumonia, one

The sequelae were bronchiectasis, four (8 per cent). The results of treatment were cured, twenty-eight (56 per cent), improved, eleven (22 per cent), died, ten (20 per cent), unimproved, one (2 per cent)

In this connection, attention is invited to a preceding paragraph giving the various results of treatment by other writers

Detailed results of treatment other than medical are given in table 1. Some of these patients had more than one surgical procedure. Table 1 embraces five fatal cases.

By "cured" is meant those patients with no remaining clinical or gross roentgen evidence of pulmonary pathologic changes. By "improved" is meant those patients leaving the hospital against advice before their conditions were entirely cleared up clinically or roentgenographically (a small proportion) and those who, remaining in the hospital to complete the period of treatment, had recovered clinically but whose roentgenograms showed some residual pathologic condition in the nature of fibrosis or bronchiectasis. Generally, these cases may be considered as having obtained a satisfactory result with much less scarring and loss of function of the pulmonary tissue than would result from incision and drainage.

The number of cases completed by medical treatment alone was thirty-four, or 68 per cent of the total number. Of these patients, twenty, or 40 per cent, were cured and nine, or 18 per cent, were improved. Five, or 10 per cent, died, two of them having refused surgery. Of the multilocular cases, one was cured and three were improved. Of these three patients, two left the hospital against medical advice, markedly improved and might well have gone on to a cure.

The causes of death in the ten cases are given in table 2. It would seem that the third fatal case, which occurred three days after admission, should hardly be charged against the hospital mortality.

TABLE 1—Results of Treatment Other Than Medical

	Cured	Improved	Unimproved	Died
Incision and drainage	3	0	0	3
Artificial pneumothorax	0	2	1	3
Bronchoscopy	2	0	0	1
Thoracoplasty	1	0	0	1
Phrenicectomy	2	0	0	0

Eight cases required adjunct measures to medical treatment to bring about cure and two cases to bring about improvement.

This gives a 20 per cent mortality or, deducting the case in which death occurred three days after admission, 18 per cent mortality. Of these, five patients died following surgical procedures (possibly initiated too late) which were necessary because of failure of medical treatment.

COMMENT

The treatment given in the cases cited was evidently not always the best advised. However, it is apparent that medical treatment, with no recourse to adjunct

treatment, furnishes a method that can be satisfactorily used by the general practitioner at little expense to the patient and in his home. If surgical procedures are indicated later, the patient should not be too ill to be moved to a hospital if decision is made at the proper time.

The results of treatment in this series should have been better, but considering the more or less changing personnel, not always alive to the importance of detail

TABLE 2—Causes of Death in Ten Cases

Condition	No. of Cases
Empyema following medical treatment, followed by incision and drainage of empyema and of the pulmonary abscess	1
Spontaneous pneumothorax following artificial pneumothorax followed by pyopneumothorax, incision and drainage	1
Suppurative pericarditis and nephritis following medical treatment (died 3 days after admission to hospital)	1
Suppurative pneumonia with extension and secondary multiple cavitation following general medical treatment	2
Multiple metastatic brain abscess following medical treatment	1
Medical treatment followed by an ill advised artificial pneumothorax, empyema, aspiration, closed drainage, open drainage, thoracoplasty, pneumotomy and septicemia	1
Artificial pneumothorax also ill advised with blocking of drainage and extension of the suppurative pneumonia	1
Artificial pneumothorax which was unsuccessful on account of adhesions, bronchoscopy, septic bronchopneumonia with refusal of surgery when advisable	1
Following failure of medical treatment, surgery refused with empyema, bronchopulmonary fistula and septicemia	1

in treatment, and an occasional uncooperative patient they seem fairly satisfactory.

There should have been more caution employed in the use of artificial pneumothorax and more use made of bronchoscopic drainage. Some of the cases that were sent on to operation might have cleared up without it with a greater use of the bronchoscope. It is perhaps best not to speak of "cure" in abscess cases, especially when the case is not followed long enough to determine whether a recurrence may take place, but it seems necessary to use some term more forceful than "improved" to describe certain cases.

Pneumonia is cited by some writers as an infrequent precursor of abscess, but my experience, following careful questioning of patients coming into the hospital with a developed abscess, would indicate that probably a pneumonic process of some nature had been present in approximately one third of the cases.

CONCLUSIONS

1. More than 50 per cent of acute pulmonary abscess cases can be brought to a satisfactory conclusion by medical treatment alone.
2. The essential feature of medical treatment is "postural drainage."
3. The treatment is so simple that it can be carried out at the patient's home by the general practitioner so long as adjunct measures are not required.
4. Bronchoscopic drainage is an important adjunct to the medical treatment of acute lung abscess.
5. The recognition of the limitations of medical treatment and the decision as to when surgery is advisable are important and responsible requirements.
6. An appreciation of the difference between acute and chronic lung abscess is necessary in order to outline and carry out treatment properly.

PSEUDOXANTHOMA ELASTICUM

ASSOCIATED WITH ANGIOID STREAKS OF THE RETINA
AND DIABETES MELLITUS IN SISTERS

EUGENE S SUGG, M.D

AND

DUDLEY D STETSON, M.D

NEW YORK

Pseudoxanthoma elasticum is about as rare a condition as angioid streaks of the retina, and when the two were reported as occurring in the same patients, renewed interest was awakened among dermatologists and ophthalmologists

Pseudoxanthoma elasticum must be differentiated from the various forms of xanthoma. The latter, while present elsewhere, invading the natural creases of the skin of the neck as does pseudoxanthoma elasticum, occurs on the face, upper eyelids, palms, soles and elbows, assuming a tuberculous and striated form. Pseudoxanthoma elasticum does not invade these sites.

Microscopically, there is an absence of fatty degeneration and xanthoma cells in pseudoxanthoma elasticum. While xanthomatous tumors have been reported by McGavack and Shephardson¹ as occurring in the presence of normal and even of low blood cholesterol values, hypercholesterolemia is present in an overwhelming majority of cases. The blood cholesterol has not been reported as being frequently elevated in pseudoxanthoma elasticum. Disseminated xanthomatosis, exclusive of xanthoma palpebrarum, is a rare disease. It occurs as a complication, usually with diabetes mellitus, but may occur independently.¹ Xanthoma diabeticorum is also rare. According to the reports of Major² and of McGavack and Shephardson,¹ up to 1933 the total number of known cases of diabetic xanthomas was ninety-seven. Diabetes mellitus, while it occurred in the two cases described here, has not been reported as occurring with pseudoxanthoma elasticum sufficiently often to be of any significance.

One point of similarity is that diabetes mellitus and the various forms of xanthomas are known to have a definite hereditary history and, from the reports of pseudoxanthoma elasticum, there seems to be a tendency of it to occur in other members of the same family.

To Darier³ is given the credit of first describing in 1896 pseudoxanthoma elasticum as a separate clinical entity.

Rigal⁴ in 1881 and Balzer⁵ in 1884 described this rare skin disorder but considered it a variant of xanthoma in which there was a degeneration of the elastic tissues. The circumscribed patches of small yellowish tumors and cream colored linear markings bore a strong resemblance to xanthoma. Accompanying this was the marked relaxation of the skin, hence the name pseudoxanthoma elasticum, which dermatologists consider

today to be a misnomer. Darier⁶ employed the term "elastorrhæxis of the skin," which is now believed to be much more descriptive of the disease.

One of the most outstanding characteristics of pseudoxanthoma elasticum is the loose, relaxed and wrinkled appearance of the skin of the neck and axillae. In addition are observed multiple cream colored, subepidermal nodules varying in size from a pinhead to a large pea. Many of these are discrete, but the smaller ones appear to have coalesced, producing whitish and yellowish striae of varying widths and lengths. On the neck, these striae are much longer and wider and invade the natural creases of the skin. The eruptions have been observed in the mucous membranes of the mouth and nose in two instances, and also on the back and extremities occasionally. The face, scalp, palms and soles have never been reported as being involved.

Another type of lesion of pseudoxanthoma elasticum is the irregularly shaped blotch of varying size described as occurring on the skin of the chest, shoulders and arms. These plaque-like areas present a reticulated, yellowish, mottled appearance. On first inspection these blotches appear to be elevated, but when the skin is

Fig 1 (case 1)—Puckering of skin in the axillae in a case of pseudoxanthoma elasticum of thirty years duration

stretched it is found to be smooth, and the areas are really subepidermal. The skin in these areas shows some loss of elasticity, but to a much less extent than the skin of the axillae and neck. There is atrophy of the skin in all these areas.

As the disease progresses, in some cases whitish scar-like markings appear in the abdominal skin which have a striking similarity in appearance to lineae albicantes following pregnancy. From this it can be seen that the lesions are of many types and may appear in widely different areas.

Pathologically, the elastic fibers in the deep portions of the skin appear to undergo an extensive degeneration. The elastic tissues are curled and broken, and they stain darkly.

Macleod states that, microscopically, sections show that the nodule is due to the presence of a mass of swollen and fragmented elastic tissue fibers situated in the reticular part of the corium, which gives the staining reaction, either of healthy elastin or of its degenerated product, elacin. Giant cells though not always present have been observed in which the nuclei were not

arranged in a ring or horseshoe fashion, as the giant cells of tuberculosis, but formed a cluster within a mass of faintly stained protoplasm. The sweat, sebaceous and hair glands are normal.

Until recently, this degeneration of elastic tissue was considered characteristic of pseudoxanthoma elasticum, but Kissmeyer and With⁷ and Weidman⁸ in their studies of senile skin, old scars and lineae albicantes observed similar elastic tissue degeneration. Weidman, after further study of senile skin, concluded⁹ that pseudoxanthoma elasticum was almost identical with some specimens of senile elastosis. Montgomery¹⁰ was of the opinion that, by using Unna's differential stains the typical case of pseudoxanthoma elasticum could be

Fig. 2 (case 2)—Front view of neck in case of pseudoxanthoma elasticum showing relaxation and folding of the skin with parallel striae.

readily distinguished from senile changes in the skin. Jones, Alden and Bishop,¹¹ in their report, stated that histologically the two conditions could not be differentiated. Because of this close relationship, these observers were of the opinion that pseudoxanthoma elasticum was an evidence of presenility. From these observations it seems apparent that elastic tissue degeneration is not confined entirely to pseudoxanthoma elasticum.

Angioid streaks of the retina were first described by Pflege¹² in 1892. The same year, Knapp¹³ introduced the term "angioid" in describing streaks of the retina which he observed. Doyme¹⁴ in 1889, however, had reported his observations in a case quite similar to this condition, and for this reason his name will always be associated with the early discovery of angioid streaks. On ophthalmoscopic examination, a reddish brown band is noted around the border of the optic disks, from which radiate vessel-like streaks, some of which are curled or corkscrew shaped. These are found in the subretinal area. As the disease is a progressive one there is a constant change in the ocular picture, the color of the streaks varying from time to time from a pale red to red, brown and black. May¹⁵ describes the angioid streaks as "dark brown, pigmented striae, resembling obliterated blood vessels, and probably the sequelae of hemorrhages." Sooner or later there is a disturbance in vision. No complete pathologic examination has been made of the angioid streaks, and the etiology is unknown, although many conflicting theories have been offered.

Since the first report of pseudoxanthoma elasticum by Darier in 1896 and the description of angioid streaks of the retina by Pflege in 1892, very little additional information had been added to the knowledge of the nature of these rare diseases until 1929. In that year Gronblad¹⁶ and Strandberg¹⁷ were the first to report angioid streaks of the retina, occurring in three patients who also had pseudoxanthoma elasticum. Gronblad¹⁸ in 1932 reviewed all the reports of combined pseudoxanthoma elasticum and angioid streaks and was of the opinion that a new disease syndrome had been established in which the elastic tissues underwent degeneration. This degeneration, while it was usually confined to the skin and mucous membranes, was also found to affect the elastic tissues of the eyes and circulatory system. Lewis and Clayton¹⁹ in 1933, in an excellent review of this subject, reported, including their own case, seventeen cases in which both pseudoxanthoma elasticum and angioid streaks were demonstrated in the same patients. These investigators endorsed the opinion expressed by Gronblad and suggested that the term "elastosis atrophicans" be used to designate the syndrome of these combined diseases. They had no explanation of the etiology other than that of a hereditary predisposition. These observers reported improvement of the affected skin of the neck by treatment with roentgen rays but were unable to get a biopsy afterward. Jones, Alden and Bishop¹¹ in their report did not find the association of angioid streaks and pseudoxanthoma elasticum to be the invariable rule, as they found that either one or the other might occur independently. This was further confirmed by Gronblad,²⁰ Perkins²¹ and other observers. In our opinion, a sufficient number of cases have not been studied to justify fully the estab-

lishment of a new disease syndrome or to throw any light on the etiology. None of these cases have ever been noted to assume any malignant characteristics.

To the seventeen cases already reported of pseudoxanthoma elasticum associated with angioid streaks of the retina in the same patients, we add our two cases occurring in sisters, who also have diabetes mellitus.

REPORT OF CASES

CASE 1—History—Mrs A C, an Italian housewife, aged 41, seen at the diabetic clinic in 1930, first noted blurred vision in her left eye about three months before, which grew gradually worse. On examination at the New York Eye and Ear Infirmary she was found to have diabetes mellitus and was referred to our clinic. There was nothing of importance in the past history except the failure of vision in her left eye and the skin disorder of the neck and axillae, which had been present for twenty years. Although it had given her no symptoms, the involvement of the skin had gradually grown more extensive. During this time she had visited many hospitals and physicians without any beneficial results. She has seven healthy children and her father, mother and two brothers are all in good health. One sister (patient 2) has a similar skin condition and diabetes mellitus. She has been a very cooperative patient, and the diabetic condition is now properly controlled. The peculiar relaxed and wrinkled condition of the skin of the neck and axillae was noted, and a diagnosis of pseudoxanthoma elasticum was made in the department of dermatology.

A careful physical examination did not reveal any abnormalities except blindness in the left eye, the skin condition and a rather low blood pressure, 100 systolic and 80 diastolic. There was no evidence of any lesions of pseudoxanthoma elasticum in the nose or mouth. The scalp, face back, legs, palms and soles were free from disease. The throat was normal, and all the teeth were artificial. On examination, the heart, lungs, abdominal viscera and nervous system were found to be normal. Menstruation was normal, and the gynecologic examination was negative. Her present weight of 120 pounds (50.5 Kg) has been constant for the past three years.

Ophthalmologic Examination—This was made by Dr O P Perkins, who reported angioid streaks of both retinas. A brownish ring almost surrounded the right disk, from which extended brownish colored branches. In the left eye there was also noted evidence of an old retinitis, which more or less obscured the angioid streaks, but a few definite ones were visible. She could distinguish only darkness from light with the left eye, and the vision in the right was 20/20 uncorrected.

The cutaneous lesions in the two cases will be described together after the report of case 2.

Laboratory Report—A diet was given to the patient consisting of 140 Gm of carbohydrate, 60 Gm of protein and 70 Gm of fat. Following this the blood sugar did not rise above 150 mg per hundred cubic centimeters, and the urine rarely showed dextrose. The blood chemistry, which was normal, was creatinine, 12 mg per hundred cubic centimeters, urea nitrogen 17.3 mg, and blood sugar 168 mg. The Wassermann test was negative and the blood count was normal.

CASE 2—History—Mrs J M, an Italian housewife, aged 44, appeared at the diabetic clinic in 1933 at our invitation because we were told by her sister (patient 1) that she had a similar skin disorder of over ten years' duration. There was nothing in her past history of importance except the skin condition of the neck and armpits. She had had no symptoms but the lesions had grown more extensive. Many physicians had observed her, but no treatment had been recommended. She has three healthy children living and three dead. A routine blood chemistry examination and a urinary analysis were made and diabetes was discovered. The peculiar appearance of the skin of the neck and axillae was noted to be almost identical with case 1 and a diagnosis was made as before of pseudoxanthoma elasticum. No other physical abnormalities were found except an elevated blood pressure 160 systolic and 80 diastolic and a constant systolic murmur at the apex which was transmitted to the axilla. Her weight of 120 pounds (50.5 Kg) has been constant for the past few years.

Ophthalmologic Examination—This was made by Dr O P Perkins. The uncorrected vision of both eyes was 20/20, and external examination showed nothing of importance. A typical fundus picture was noted with angioid streaks of the retina. Both disks were partially surrounded by brown zones and extending outward from these were noted brownish and red striae of varying lengths, some of which branched and all appeared under the retinal vessels.

Laboratory Report—On admission in July 1933 the blood sugar was found to be 250 mg per hundred cubic centimeters, and the urine contained 1 per cent sugar. She was given a diet of 150 Gm of carbohydrate, 60 Gm of proteins and 75 Gm of fat. The blood sugar following this was found to be 180 mg per hundred cubic centimeters, and the urine became sugar free. The blood chemistry, which was normal, was as follows: blood cholesterol, 166.5 mg per hundred cubic centimeters, urea nitrogen, 19.40 mg, and creatinine, 15 mg. The blood count was normal and the Wassermann test was negative.

Fig 3 (case 2)—Side view of neck.

Cutaneous Examination—The peculiar folding, wrinkling and relaxed state of the skin of the front and sides of the necks of the two sisters were almost identical. The elasticity was lost to such an extent that the skin could be caught between the fingers and folded, thus producing the effect of being too large for the area which it covered. In both cases the axillary skin was likewise loose, baggy and velvety to the touch. The lesions in case 2 were confined to the neck and axillae. Multiple soft, yellow, subepidermal nodules were noted which varied in size from a pinhead to a pea and larger. These appeared to be elevations, but on palpation or stretching the skin was found smooth. The color of the nodules varied from a lemon yellow to cream, and on the neck many of those of pea size had coalesced to form larger ones, which were of a more pronounced yellowish hue and distinct in outline. Buff colored linear markings which apparently had been formed by the coalescence of the minute nodules had invaded the natural creases of the skin of the neck producing the effect of streaks or lines. In case 1 the cutaneous condition was not confined to the neck and axillae as in case 2, but areas of involvement were noted on the shoulders, arms, chest, cubital fossae and

abdomen The loss of elasticity, though present, was far less in these regions than in the neck and folds of the axillae

A reticulated network of cream colored streaks was noted on the posterior surface of the neck in case 2, where the skin was not smooth, and also a similar irregular area on the left shoulder in case 1, with an indefinite outline shading off into the natural color of the skin On stretching, these lesions became more distinct and appeared to be composed of multiple pinhead sized yellow tumors, arranged in a meshlike manner within the skin, producing a mottled appearance A yellow, plaque-like blotch was present on the chest above the left nipple and also one was observed on the right arm in case 1 Scratched over the cubital fossae and abdomen were found faint yellow scarlike lines and whitish striae, the latter over the abdomen, resembling linear albicantes The individual tumors or nodules forming these lines, while much smaller, were similar to the eruptions noted in the neck and axillae There was no evidence of a lilac hue of the skin described by Darier In both patients there was a noticeable overgrowth of hair on the face

HISTOLOGY OF THE CUTANEOUS LESIONS

Specimens of skin were removed from the posterior axillary fold in both cases and studied by Dr Lawrence Saphran who reported as follows

Microscopic examination in case 1 revealed an epidermis of normal appearance as to cell constitution but the rete pegs were very short There were no hair follicles or sebaceous glands but the coil glands were normal The fibrous tissue had the usual collagenous constitution without degeneration or edema Sections stained for elastic tissue by Weigert and by Verhoeff's stain revealed a small amount of delicate fibrils immediately under the epidermis There was a rather sharp line of demarcation between the superficial dermis and the deeper two thirds The latter part had in it small segregated clusters of elastic substance in the form of coarse fibrils and knots The continuity between the deep and superficial elastic tissue appeared broken The blood vessels were of normal form No inflammatory infiltration or giant cells were present

The epidermis in case 2 was somewhat thinned out and presented very fine wrinkles There were no rete pegs The fibrous tissue was of the usual density and the collagen was

Fig 4 (case 1)—Section of skin from posterior axillary fold Verhoeff's elastic tissue stain used The elastic tissue in the deeper two thirds of the dermis is in broken contracted knots and heavy short coils The superficial dermis has small delicate fibrils and the epidermis appears in redundant folds Collagen is not degenerated Accessory glands of the skin appear normal Note the demarcation of the two portions of the dermis caused by the difference in the elastic constitution Reduced from a photomicrograph with a magnification of 100 diameters

free of degeneration and edema Coil glands were present and appeared normal Section stains for elastic tissue revealed long delicate fibrils only in the superficial portions of the corium The deep half contained separate broken and contracted bundles of elastic tissue mainly knotted together and without continuity The blood vessels were normal No inflammatory infiltration or giant cells were present

The pieces of skin from the two patients showed a definite degeneration and fragmentation of the elastic tissue, so that the superficial portion of the corium and epidermis had become separated from the deep portion of the skin There was no evidence of calcification, giant cells or involvement of the blood vessels The close resemblance between the pseudoxanthoma and senile elastosis described by some observers could not be demonstrated The collagen fibers did not show the alteration seen in senile skin, and the marked deterioration of the elastic tissue was not present in senile elastosis

Fig 5 (case 2)—Section of skin from posterior axillary fold Verhoeff's elastic tissue stain used The elastic tissue of the superficial portion of the dermis is in delicate slender fibrils A gradual thickening and fragmentation of the fibrils is seen in the deeper dermis and some zones have the typical dense separate coils of fibrils broken apart Reduced from a photomicrograph with a magnification of 100 diameters

CONCLUSIONS

Pseudoxanthoma elasticum and angioid streaks of the retina are both rare diseases Up to the beginning of 1934, only seventeen cases had been reported in which these conditions occurred in the same patients To this number we have added the reports of two cases in sisters with these diseases combined, and also diabetes mellitus

No evidence as to the etiology of pseudoxanthoma elasticum has been discovered Some writers express the belief that a hereditary predisposition is present, and others express the opinion that, because of the close resemblance to senile elastosis, pseudoxanthoma elasticum is an evidence of presenility No satisfactory pathologic examination has ever been made of angioid streaks of the retina, and the etiology is unknown The latest suggestion is that it is a part of a generalized process of elastic tissue degeneration, involving the skin, circulatory system and eyes The disease is progressive, and sooner or later vision is impaired There has been reported no satisfactory treatment An insufficient number of cases of diabetes mellitus in combination with pseudoxanthoma elasticum have been reported to be of significance, except that the familial tendency of diabetes mellitus is well known, and pseudoxanthoma elasticum has been reported in other members of the same family The occurrence of pseudoxanthoma elasticum and angioid streaks of the retina in the same patients is frequent and striking, but we are unable to agree that a new disease has been established No treatment of pseudoxanthoma elasticum has met with any success except in the case reported by Lewis and Claverton¹⁹ in which the skin of the neck was apparently improved by means of roentgen rays

CALCIFICATION OF THE TIBIAL COLLATERAL LIGAMENT

A REPORT OF FORTY-TWO CASES

JEROME G FINDER, MD
CHICAGO

Calcification or ossification in the tibial collateral ligament is a relatively frequent clinical entity the significance of which has heretofore been unrecognized or ignored Pellegrini-Stieda's lesion constitutes the major part of the material in this paper Kulowski¹ recently reported the first case in the English literature, although about 150 cases had been recorded previously in European publications Kohler described the condition in 1903, but Pellegrini in 1905 and Stieda in 1907 were the first to study and report its clinical significance Petrignani² reviewed the literature in 1931 and added several of his own cases

I am reporting observations made in a series of forty-two roentgenologically proved cases of either calcification or ossification of the tibial collateral ligament I will suggest a classification of various types of this lesion and present a theory of its etiology and pathologic manifestations

Most of my material was collected from the files of the department of orthopedic surgery, Cook County Hospital, Chicago, and represents cases admitted over an eighteen months period to the services of Drs Philip Lewin, E J Berkheiser, M H Hobart, P H Kreuscher and D H Levinthal Dr C H Warfield, chief of the department of roentgenology, assisted with the roentgenographic interpretations Three cases were added to my series through the courtesy of Dr Arthur

involved Four groups are considered, the first of which corresponds to Pellegrini-Stieda's lesion in its classic and varied forms, the subsequent three groups are here described for the first time

1 *Proximal Area of Calcification*—This group represents twenty-eight cases of Pellegrini-Stieda's lesion, the largest series in the English literature The roentgenograms reveal a semilunar shadow overlying, but usually distinctly separate from, the medial femoro-

Fig 2—Group 2 A condition in a male B in a female C destruction of the knee joint and bones from infection following a gunshot wound with secondary ligamentous calcification group 4

condylar angle Depending on the degree of ligamentous involvement, the shadow may be crescentic, triangular or fusiform It may be limited to the condylar region or extend distally toward the joint (fig 1) Andreesen³ recently reported thirty cases, which he classified into three groups The first was characterized by a calcified strip, continuous or interrupted, along the inner condyle of the femur, these lesions occurred in persons between the ages of 29 and 41 years The second group showed a more extensive, shell-like, irregular shadow In the third series rather large areas of ossification, in direct contact with the inner condyle were present The age group ranged from 38 to 52, usually there was greater trauma and an associated hypertrophic arthritis I recognize these types and consider them subdivisions of my group 1

2 *Central Area of Calcification*—The eight cases in this group are characterized by a calcified, pea-sized nodule in the mid-portion of the ligament, usually just proximal to the joint space or occasionally opposite it (fig 2 A, B)

3 *Combined Areas of Calcification*—This series of four cases combines the characteristic features of groups 1 and 2

4 *Irregular Areas of Calcification*—In this type there is secondary involvement of the tibial collateral ligament by extension of disease from inflammatory processes in the adjacent structures (bursae, tendons, ligaments, synovia and bone) Two examples of this type are included in my series The first is a case of osteomyelitis of the bones of the knee following a gunshot wound, the second is a case of postoperative suppurative arthritis (fig 2 C)

Fig 1—Cases of group 1 (Pellegrini Stieda type) A moderate involvement of the tibial collateral ligament in a woman aged 50 B marked calcification in a man corresponding to the second type of Andreesen C slight process in a girl aged 12

Steindler, from the files of the department of orthopedic surgery, State University of Iowa College of Medicine

CLASSIFICATION

I have classified the various types of calcification or ossification according to the portion of the ligament

¹ Kulowski Jacob Pellegrini Stieda's Disease J A M A 100 1014 (April 1) 1933
² Petrignani R La maladie de Pellegrini Stieda Rev d'orthop 15 105 (March) 1931

³ Andreesen Remmer Ueber den Stiedaschen Begleit chatten am inneren Oberchenfellnorren Arch f l n Chir 174 162 1933

ETIOLOGY

Incidence—About 3 per cent of the orthopedic cases appearing at our clinics because of symptoms referable to the knee showed evidence of tibial collateral ligament calcification or ossification

Race—No significant predilection was noted in the very heterogeneous group of my series

Fig 3—Peripheral portion of bony body in tibial collateral ligament as seen under low power. *A* surrounding soft tissues with zone of fibrous osteoid bone *a* and calcified fibrous bone *b* fibrous and hyaline cartilage *c*, in enchondral ossification with primary spongy bone *d* *B* lamellar spongy bone with lacunar resorption *e* and loose fibrous bone marrow, *f*

Sex—It is usually reported that women are rarely affected. As in other conditions in which exposure to trauma plays a role, the male sex naturally shows a higher incidence. However, in the complete series (as well as in group 1) the men predominated over the women in the ratio of five to two. The fact that nearly all the women were of the working class may account for the high incidence in females (figs 1 *A*, 2 *B*)

Age—Most observers report that Pellegrini-Stiedt's lesion is a disorder of adults between the ages of 25 and 40, and that it never occurs in children. My series includes a 12 year old girl with definite roentgenologic changes (fig 1 *C*). In group 1 the ages ranged from 12 to 54 years, with an average of 40.1 years, about 40 per cent occurred within the fifth decade. The age incidence in group 2 was much lower, with a mean of 28.5 years, the ages ranged from 15 to 68 years, 75 per cent being included in the second and third decades.

Trauma—Injury is almost invariably the inciting factor except in the cases in group 4. The accident may be gross, but I would emphasize that repeated minimal injuries (occupational, for example) may initiate the pathologic process.

PATHOLOGY

Pathogenesis—Calcification in ligaments and tendons has been known for many years and is mentioned in

most textbooks on orthopedics. Lewin⁴ feels that calcification or ossification of the tibial collateral ligament, which bridges across the bony prominence of the femoral condyle, protected by numerous bursae, is analogous to calcification of the supraspinatus tendon in the region of the subdeltoid bursa. Andreessen³ believes that the calcification occurs in the attachment of the adductor magnus tendon rather than in the tibial collateral ligament. Such an entity as he describes may occur, as I shall point out later, but probably it is formed secondarily by direct extension or continuity of tissue.

Three theories are held regarding the origin of the calcification: first, that it may follow a fracture with detachment of a spicule of bone at the time of trauma, second, that it is due to a fractureless callus as a result of periosteal tear and proliferation, third, that it arises from the surrounding connective tissues. It is likely that any one of these factors, alone or in combination, can cause bone formation.

Histopathology—Kulowski¹ treated his patient surgically. The resected specimen showed three types of bone growth: first, a predominant primitive infiltrative type on the basis of connective tissue, second, callus-like bone formation, third, enchondral bone formation, present to the least extent. One of the patients in my series (group 3) was operated on and specimens were

Fig 4—Extensive lacunar resorption of one marrow space in the smaller bony body (central area of group 3 case seen in figure 3 *A*) under high power. *A* young fibrous bone marrow with osteoclasts *a* in fibrous bone *B* *C* marrow spaces with older fibrous bone marrow and smooth endosteal surface with osteoid layer and osteoblasts *b*

obtained from the proximal and central areas of the ligament. Both specimens showed the presence of fibrous and enchondral bone, but no callus-like bone formation was noted, probably because of the relative maturity of the process. I am indebted to Dr. Ernst

⁴ Lewin, Philip. Personal communication to the author. Oct. 1, 1933.

Freund of Iowa City for the detailed description of the microscopic changes

Two sections were examined. The larger section (proximal area fig 3) represents essentially a bony body of rather dense spongy bone included in dense fibrous tissue. The latter is probably a part of the ligamentous structures of the inner side of the knee joint. The bony body itself is composed by fibrous and lamellar bone tissue. The distribution of the two kinds of bone tissue is usually such that the inner portion of the thick bony trabeculae is formed by fibrous bone while the peripheral layers show mature lamellar bone. The borderline between the inner and peripheral types is usually a lacunar cement line. The marrow spaces included in the spongy bone are filled with a loose fibrous marrow which gradually becomes transformed into fatty bone marrow. The endosteal surface of the bony trabeculae is uniformly smooth in all places. Only a few marrow spaces show lacunar outline with active osteoclastic bone resorption (fig 4).

The borderline between the bony body and the surrounding connective tissue shows a gradual blending of the two tissues into each other. This indicates that the peripheral layer of the bony body is almost entirely formed by fibrous bone, which toward the periphery is purely fibrous osteoid and the fibers of the surrounding connective tissue are anchored in fibrous bone as Sharpey's fibers.

In a few places the surrounding connective tissue becomes transformed into fibrous cartilage, in a few places into hyaline cartilage. This cartilage calcifies in a very irregular way and later on is invaded by small hyperemic marrow spaces. The calcified cartilage becomes resorbed and thin layers of lamellar bone are laid down on the lacunar outline of the cartilage. This is a very primitive form of enchondral ossification in which practically no proliferation of cartilage cells occurs. A rather dense and coarse spongy bone results whose trabeculae include small particles of calcified cartilage even at remote distances from the area of enchondral ossification.

In the smaller specimen (central area) the fibers at one margin of the ligament gradually become impregnated by an osteoid substance, thus forming a primitive fibrous bone which becomes calcified later. In the early stages of the process there is very little difference in structure between the fibrous tissue of the ligament and the fibrous bone. Later however, the cells included in the fibrous bone assume the appearance of osteocytes.

Comment. The picture in the first instance is that of a more mature and longer existing bone production in the par-articular tissues. The bone production is actually more or less at a standstill. Only at the periphery a very slow progression or expansion of the bony growth can be noted. This occurs by infiltration of the surrounding connective tissue with osteoid ground substance. Enchondral ossification is present but does not form by any means a striking feature. The second specimen represents essentially the same process in an early stage in which no lamellar bone is seen.

SYMPTOMS

The symptoms of calcification or ossification of the tibial collateral ligament are not pathognomonic of the lesion but are common to most injuries about the knee. A history of trauma however slight, must not be ignored. Pain is referred to the medial aspect of the knee joint. Complete extension while possible, is painful owing to tautness of the injured ligament. Consequently the knee is usually held in slight flexion for some time after the injury. Transitory swelling about the knee joint may be observed. Occasionally it is possible to palpate the calcified area.

Before the diagnosis can be made it is necessary to consider such accidents as fracture of a semilunar cartilage rupture of a cruciate ligament avulsion of the tibial spine and detachment of the tibial tubercle. In the event of persistent pain or of tenderness to palpation over the medial side of the knee one must

suspect injury to the tibial collateral ligament. The mechanism that produces an internal derangement of the knee may also cause a concomitant injury to the ligament. The presence of one, therefore does not necessarily exclude the existence of the other. Roentgenograms made ten days after the injury may be suggestive, a well defined shadow may be present after three weeks.

TREATMENT

No definite surgical procedure has been suggested thus far. Conservative measures are usually advocated: rest during the acute stage, physical therapy later. It is likely that many untreated cases heal spontaneously, without prolonged disability or symptomatic residuums. This is borne out in three cases in which discovery of calcification in the ligament was made incidentally. On repeated questioning, however, a remote injury could be recalled.

In the case treated surgically by Kulowski the growth recurred. In my case the excess new bone formation of the proximal portion of the ligament and the calcified central nodule were resected, followed by plastic repair of the ligament. After five months, the patient had a full range of symptomless motion. At that time the roentgenogram revealed interesting changes. The proximal area of calcification showed no tendency to regrowth, in fact, there seemed to be some resorption of the residual mass. However, a tangential calcified spur was seen arising from the mediosuperior margin of the condyle, corresponding to the insertion of the adductor magnus tendon. The distinction between this picture and that of calcification or ossification of the tibial collateral ligament tends to refute Andriessen's theory. The roentgenograms also revealed two new areas of calcification in the central part of the ligament.

It seems reasonable to believe that a plastic lengthening of the ligament which relaxes the tension without unduly influencing its lateral stability, will alleviate the pain in cases resistant to other forms of treatment.

COMMENT

The relative frequency with which calcification or ossification occurs in the tibial collateral ligament warrants its recognition as a clinical entity in the differential diagnosis of traumatic lesions about the knee joint. With attention focused on this lesion, many cases that previously went unrecognized or undiagnosed will be made available for study. Research should be directed particularly toward determining the pathologic process.

The task of developing a satisfactory plan of treatment devolves on the clinician.

SUMMARY

- 1 Forty-two cases of calcification or ossification of the tibial collateral ligament were observed and classified.
- 2 A group of twenty-eight cases of Pellegrini-Stieda's lesion is included in this series.
- 3 The lesion is relatively frequent and trauma plays an important role.
- 4 A further study of the pathologic changes reveals ossification as well as calcification of the ligament.
- 5 Plastic repair of the tibial collateral ligament is recommended as a form of treatment worthy of consideration.

ACQUIRED SENSITIZATION TO SODIUM ISOAMYLETHYLBARBITURATE (SODIUM AMYTAL)

AS EVIDENCED BY CUTANEOUS ERUPTIONS
REPORT OF FOUR CASES

ALFRED M. LANGENBACH, M.D.
ST. LOUIS

In 1923 Shonle and Moment¹ announced the synthesis of various new barbituric acid derivatives. In one group, designated as the dialkyl group, the isoamylethylbarbituric acid (amytal) was found to have the greatest hypnotic powers.

The sodium salt of this acid was prepared in 1926² and thoroughly introduced to the medical profession, since which time it has seen an extensive usage in anesthetics, medicine, obstetrics and surgery. This salt differs from the sodium salt of diethyl barbituric acid (soluble barbital) in that in the former an isoamyl group replaces one of the diethyl groups of the latter. With the exception of this difference in chemical composition the two drugs are chemically identical. In the cases to be reported here it will be indicated how such

years later. During the year that followed, the use of the latter preparation was first reported³ and almost immediately reports began to appear⁴ on the toxic effects noted.

Year after year these reports have actually piled up regarding the various toxic effects noted, of which the skin reactions have been in no minority. This is true not only of phenylethylbarbituric acid but of all of

Fig 1—Eruption on face in case 1

a difference in radicals produces differences in reactions in man.

Fischer and von Mering³ introduced the first dialkyl barbituric acid (veronal) to medicine in 1903. The phenylethylbarbiturate (luminal) was introduced nine

Fig 2—Eruption on arm in case 1

the barbiturates used today with the exception of the sodium salt of isoamylethylbarbiturate (sodium amytal). A hasty perusal of the literature revealed no reports of toxicity evidenced by a skin rash due to this barbiturate, and Lundy⁶ in a thorough, exhaustive review of the barbiturates even makes no mention of toxic skin reactions resulting from the use of this preparation.

With this in mind I felt that the following cases warranted presentation.

REPORT OF CASES

CASE 1—A L, a man, aged 32, began taking sodium isoamylethylbarbiturate (sodium amytal) in 1929 for the induction of sleep. He was in good health but experienced difficulty in getting to sleep, owing to business and domestic worries. The capsules were taken at the rate of one 3 grain (02 Gm.) capsule each night and as often as seven nights a week. He experienced sound sleep, awoke with no residual effects, and experienced no toxic reactions afterward.

As causative conditions began to correct themselves the nightly dose became triweekly, biweekly, weekly and then at irregular intervals. Finally about the summer of 1931 the drug was discontinued entirely and no further use was made of it until the winter of 1932. At that time business worries again caused sleepless nights and he turned to the same capsules which had helped him to sleep before.

Nine hours after taking the first capsule he noticed a reaction in the form of a skin rash. He was seen on the morning following the taking of the first capsule and was found to have a blotchy eruption about the face and arms. The rash was macular, some of the macules being as large as a dime (18 mm.). The macules were sparsely distributed about the arms but were closer about the face. They were a bright rose did not itch and were more closely distributed on the right side of the parts mentioned. When pressure was applied they faded somewhat but not entirely. The mucous membrane

of the upper lip contained several patches and the lip was edematous. These lesions were somewhat indurated in contrast with the skin lesions. There was also edema about the lower eyelids. In this case there were no vertigo, eye disturbances, pruritus, cyanosis, acceleration of pulse rate, or disturbances of the nervous system, the respiratory tract or the urinary system. The urine was entirely normal. The rash lasted about three days and then gradually faded away over a period of seven days leaving a brownish pigmentation and a slight scaling at the site of each macule. The edema of the lip lasted about a week.

He was confident that the rash was due to the capsule that he had taken but was at a loss to explain why he had not experienced a similar reaction when the same capsules were taken about two years previously. He was thereby induced to resume the use of the capsules when indicated.

Thus he did. About six weeks later he took another capsule containing 3 grains of sodium isoamylethylbarbiturate on retiring. He slept well and awakened refreshed but exhibited the same skin eruptions to even a greater degree than the first display. The rash was identical with the first in appearance but more macules were present.

Sept 2, 1933 in a desperate attempt to get to sleep he disregarded all his former experiences and took a third capsule of the same dose. On awakening the next morning he looked at once for the eruption and was not disappointed. The rash this time was of about the same intensity and was distributed to the same locations as the former rashes, i. e., the face, neck, lips and upper arms. The rest of the body was free of any eruption. Other physical and chemical observations were made at this time and will be presented in a future report.

He was urged to use isoamylethylbarbiturate (amytal), not the sodium salt as before. With this he experienced an identical eruption but not as intense as with the sodium salt.

The idea that some impurity in the drug might be causing the eruption prompted a chemical analysis. No impurities were reported found.

With these observations made, my interest was aroused to see whether this acquired sensitivity extended to and included the other barbiturates as noted by other observers. He was tried on phenylethylbarbituric acid (luminal) and experienced no rash nor other toxic symptoms. At the present time he is taking the latter preparation nightly.

CASE 2—D L, a woman, aged 27, married and employed as a clerk, first began taking sodium isoamylethylbarbiturate in 1930 on the advice of her physician. The drug was taken at irregular intervals for the induction of sleep. An average of one 3 grain capsule twice a week was continued for about fourteen months. No ill effects were noted on the mornings following the taking of the capsules and no resultant evidences of sensitivity of any kind were observed. At no time did a rash appear during this period.

After using the medicine for the time stated she discontinued the capsules entirely for a period of about a year during which time she took no medicine whatever. She then returned to her physician because of nervousness and insomnia. He again prescribed the sodium isoamylethylbarbiturate in 3 grain doses.

The physician was called the morning following the taking of the first capsule to see 'a breaking out'. This rash was identical in distribution and appearance with that described in the first case.

A second capsule taken three weeks later produced a similar skin reaction the following day. By this time she was confident that the new pills were causing the rash. She was informed that the medicine would be changed and isoamylethylbarbiturate (amytal) was ordered. This likewise produced a rash within twelve hours after the ingestion of the capsule. The rash however was not as intense nor was it as thickly distributed as were the previous rashes resulting from the sodium salt. The edema of the lip was also much less.

She was then tried on phenylethylbarbiturate (luminal) but no skin reactions resulted. The latter preparation she is taking

at the present time with no evidences of toxicity or allergic reactions to date. As far as can be determined, she has never taken any barbiturates other than those mentioned.

CASE 3—A M, a man, aged 28, married and employed as a grocery clerk was ordered to take sodium amytal in 1931. He took about 120 capsules of 3 grains each during the period of one year. Never did he take more than one capsule during any twenty-four hour period. The physical condition requiring the drug subsided and he discontinued it entirely for a period of ten months, during which time he took no drugs other than tincture of digitalis in small doses.

One morning he presented himself for the inspection of a rash and "a swelling of the lip." On questioning he affirmed that he had taken no medicine other than digitalis and "one blue capsule" (sodium isoamylethylbarbiturate) the night previously. The rash was similar to that in the two previously cited cases but was more thickly distributed and the edema of the lip was more intense. It was suggested that the rash "might be due" to the capsule and it was suggested that he try another of the capsules in two or three weeks after the rash had disappeared. Thus he did with a resultant rash within twenty-four hours identical with his first eruption. Since then he has flatly refused to take any other capsules because his facial appearance and the rash interfered too seriously with his business. No other barbiturate has been used in this case and no rash has since appeared on the skin.

CASE 4—Mrs S E, aged 23 was first seen because of a missed menstrual period shortly after marriage. A diagnosis of pregnancy was made and the patient was so informed. Numerous nervous and mental manifestations promptly resulted from the realization of her condition. Worry over financial matters and fear of the delivery caused almost a complete breakdown of what was to begin with none too good a nervous system. Sodium isoamylethylbarbiturate was ordered to be taken in 3 grain doses at nights when necessary. About three or four such capsules were taken weekly with the desired good results. No toxic action or reactions were noted at any time during this period of about four months.

The child was delivered at term and for the delivery three capsules of 3 grains each of sodium isoamylethylbarbiturate were used. No other drugs were taken following this for a period of thirteen months. No eruption was seen during this entire period.

After thirteen months a second child was delivered and four of the 3 grain capsules of sodium isoamylethylbarbiturate were given to her during an eight hour period. No other drugs were used.

When she was seen the next day (eighteen hours after the first capsule) a rash had developed about the face and lips similar to that previously described except that the macules were smaller and less profuse. There were only a few lesions about the body, most of the eruptions being on the face and arms. There were a few lesions on each hand. This rash was also lighter in color and left very little pigmentation when it faded. No other drugs were used during the delivery and no eruption has since been seen. She has not taken any of the capsules of sodium amytal since so that no check has been made in this case. Like the others her rash also went through the scaling process.

The child's skin showed no eruption at any time.

SUMMARY

In four cases a sensitivity to sodium isoamylethylbarbiturate developed as evidenced by skin eruptions. These eruptions were distributed chiefly on the face, neck, arms, hands and mucous membranes of the lips and mouth.

None of the cases cited showed any sensitivity to the drug when it was first administered. The sensitivity developed during a period of from eight to fourteen months after the drug had been taken and then discontinued.

The primary use of the drug ranged from nine months to two years. The average 3 grain dose was

never exceeded in three cases. Twelve grains was used in one case during a period of eight hours.

This sensitivity differs from that previously noted⁷ in that it does not extend to other barbiturates.

5427 Southwest Avenue

Later in 1921 the patient had pleurisy with effusion on the left side, for which she received treatment in a sanatorium for two years. She was discharged symptom free at that time.

She was then well until January 1927. At that time a large gland appeared in the left groin and a few days later an abscess pointing in this region was aspirated. Aspiration was

AN ATYPICAL CASE OF TUBERCULOSIS OF THE SPINE

CHARLES K. PETTER, M.D., OAK TERRACE, MINN.
AND
J. P. MEDFELMAN, M.D., MINNEAPOLIS

This case is presented because of the unusual lesions observed in the spine. Tuberculosis of the spine usually presents a typical roentgenologic picture and its diagnosis is ordinarily not difficult.

REPORT OF CASE

History.—A white woman, aged 50, entered Glen Lake Sanatorium, Nov. 18, 1931, with the following complaints: (1) discharging left ear and enlarged cervical nodes, (2) loss of weight and weakness, (3) a mass in the left lumbar region, (4) fever and chills accompanied by occasional night sweats.

Fig 1—Lower dorsal and lumbar spine. A as observed roentgenographically. B diagrammatically, showing lesions in detail.

The cervical adenitis was first noted in July 1931, following a mastoid operation. However, it was later recalled that a few slightly enlarged glands were present before the operation. The left ear had been discharging since the mastoidectomy.

Loss of weight amounting to 25 pounds (11.3 Kg.) and weakness had been gradual over a period of two years.

The mass in the lumbar region to the left of the spine was first discovered about a year before admission. Since that time it had become progressively larger.

The patient stated that she had had occasional night sweats for the past six months and that chills and fever had occurred at varying intervals during the same length of time. During this time she also noted that her temperature sometimes rose to 102 F.

The patient had tuberculosis of the left knee in 1909 and of the left elbow in 1912. She was treated conservatively for both and recovered with only slight limitation of motion in the elbow.

In 1921 a laparotomy was performed at which the right ovary and a cyst from the left ovary were removed. An appendectomy was also done. Examination of the tissue removed revealed tuberculosis of the right ovary, appendix, and peritoneum.

From the Departments of Orthopedics and Roentgenology, Glen Lake Sanatorium, Oak Terrace, Minn.

Fig 2—Left sacro-iliac region showing lesion near joint.

repeated several times, with evacuation of large quantities of pus. The pus was apparently not examined in a laboratory and a single anteroposterior film made of the lumbar spine is reported as having been negative.

The remainder of the past history and the family history is unimportant for the purposes of this report. There had never been any complaint leading one to suspect primary malignant tumor.

Fig 3—Anteroposterior and lateral roentgenographic appearance of vertebral bodies at autopsy.

Physical Examination.—The patient was pale and poorly nourished.

There was a scar of a mastoid operation on the left and a thin watery discharge from the left ear.

There were numerous greatly enlarged cervical lymph glands on the left with reddening of the skin over two of these and

discharge from one. On the right side there were a few smaller palpable glands 2 or 3 cm above the clavicle. A few very small glands were palpable in the axillae.

There were no abnormalities in the chest.

The liver was palpable 3 cm below the costal margin. No abdominal masses were felt. From the umbilicus to the symphysis there was a healed midline incision.

A soft tissue mass 5 by 10 cm in size was visible immediately adjacent to the upper lumbar vertebrae on the left side. The mass was firm and finely nodular. There was no redness of the overlying skin and the mass was not tender.

No complaint of pain and no muscle spasm could be elicited on movement of the spine.

There was muscle atrophy involving the left arm, with limitation of extreme flexion and supination at the elbow, but no pain on motion of the elbow joint. There was marked atrophy of the muscles of the left thigh, with free motion of the left hip and knee.

Röntgen Examination.—Only the significant observations are given. There was thickening of the pleura over both lungs, but no evidence of parenchymal pulmonary disease.

New bone formation with rounded areas of bone destruction were present in the bodies of the eleventh and twelfth dorsal vertebrae and to a greater extent in the bodies of the first and third lumbar vertebrae. There was a similar process in the left ilium near the sacro iliac joint but not involving the joint. It was concluded that the observations represented malignant metastasis, as shown in the accompanying illustrations.

The right kidney was normal in size, shape and position. The shadow of the right psoas muscle was visualized and was normal. There was a large, poorly defined density in the left kidney region, and the shadow of the left psoas muscle was obliterated. These observations were interpreted as being due to a kidney tumor or a paranephritic abscess. Because of the appearance of the spine it was felt that the weight of evidence was in favor of the former, even though hypernephroma usually gives rise to metastases that are predominantly destructive in bone.

Laboratory Examination.—On admission, examination of the blood showed 4,100,000 red blood cells, 6,600 white blood cells, and a hemoglobin of 81. A differential count showed 65 polymorphonuclears, 25 lymphocytes, 9 large mononuclears and 1 eosinophil.

Only two specimens of sputum were ever obtained. Both were negative for tubercle bacilli on smears. Examination of the urine gave essentially negative results throughout. No red blood cells were found on repeated examinations.

A negative Wassermann reaction was present.

A guinea-pig inoculated with washings from the left ear was examined, January 28, and showed tuberculosis. Tuberculosis was also present in a guinea-pig inoculated with material aspirated from a cervical gland and killed, February 11. A second pig was inoculated with material aspirated from a cervical gland. This pig was killed, May 5 and tuberculous lesions were present. The organisms were typed and found to be of the human strain.

Course in the Sanatorium.—The patient was confined strictly to bed during her entire period of hospitalization. She received routine sanatorium care and was treated only symptomatically. She was too ill for pyelography to be attempted.

About January 1, a defect was palpated in the tip of the spinous process of the second lumbar vertebra. This was visualized on films, January 16. The tip of the spinous process was removed for microscopic diagnosis. The biopsy wound healed readily. Section of the tissue removed showed clusters of tubercles. They were composed of epithelioid cells radially arranged. Occasionally one showed a central giant cell. There was lymphocytic infiltration at the periphery of the tubercles and infrequently some of them were found in the center of the tubercles. The pathologic diagnosis was tuberculosis.

Following admission the patient's temperature varied within wide limits. The daily variation was often between 96 and 103 F. During her last sixty days the temperature varied from 97 to 101.

The patient's course was progressively downhill. She died June 9, 1932 after 204 days of hospitalization.

The anatomic diagnosis from the autopsy protocol was (1) tuberculous spondylitis, (2) tuberculous peritonitis, (3) tuberculous lymphadenitis, (4) left psoas abscess, (5) pleural adhesions, (6) pericardial adhesions.

COMMENT

In this proved case of tuberculosis the roentgen diagnosis of metastatic carcinoma of a mixed osteoclastic and osteoplastic type was made. The multiplicity of the lesions was in favor of metastasis. So also was the appearance of the lesions themselves, in which there was an increase in density of the vertebral bodies together with circular or rounded areas of destruction in the bodies and their appendages. The absence of collapse of the bodies in spite of the destruction near the articular margins suggested metastatic involvement. Likewise the complete absence of involvement of the vertebral disks pointed toward the presence of metastatic carcinoma.

Tuberculosis was considered in the diagnosis but was discarded because we felt that in tuberculosis (1) the lesions would not be so widespread, (2) new bone formation would play a less prominent part, (3) there should be some vertebral collapse, and (4) the intervertebral disks could hardly have escaped destruction through extension of the process from the adjacent vertebrae.

Actinomycosis was a roentgenologic possibility, but in actinomycosis one would expect larger abscesses, draining sinuses and a primary site of involvement.

Of special interest in this case is the fact that the organisms, at least in the involved glands, were identified as being of the human strain.

A SEASONAL DERMATITIS CAUSED BY SYNERGIC INFECTION

A. J. BRIER, M.D. AND J. C. HOFMANN, A.M. TOPEKA, KAN.

History.—A boy aged 15 years, in the early part of 1933 was referred to one of us (A. J. B.) for dermatitis, which was thought to be an allergic manifestation. The onset was described as being somewhat acute, having begun five or six years before with primary lesions, starting in the interdigital spaces as groups of blisters and rapidly becoming pustular. It was reported that this followed a day spent in playing along the bank of a creek known to be polluted with sewage. The lesions appeared in "crops," undergoing their metamorphosis while others were forming. Early in their existence the vesicles contained a clear, colorless, serous fluid before they became pustules. This sequence continued: new vesicles formed as the pustules healed. The patient's hands became unsightly, causing him much mental as well as physical discomfort, since his hands itched and were very sore during an exacerbation of the trouble.

The first appearance was in the spring and progressed until the advent of summer, when the lesions cleared up. The following autumn after frost they again made their appearance and went through the same cycle—progressive vesiculation, pustulation with soreness and healing. As soon as cold weather arrived the lesions disappeared leaving but faint traces for a time. The skin then became quite normal and continued so until the following spring, when the whole process was reinitiated.

This semiannual occurrence continued over a period of five or six years except during one winter which was mild in this locality, that year the lesions lasted from the onset in autumn until the coming of hot weather. The fall before he was seen by us was the first in which he failed to note the reappearance of the dermatitis, it being deferred until the following spring.

The patient had had the ordinary diseases of childhood with no serious illness. There was no history of food disturbances, headaches, hay fever, asthma or other common allergic symptoms. Also the family history was essentially negative. The patient was found to react to none of the food or inhalant groups. The Wassermann reaction was negative.

On examination, vesicles and pustules were found on the backs of each hand particularly on the medial and lateral borders, on the dorsum of the fingers and in the interdigital spaces. The vesicles had some tendency to clumping but no confluence was observed. Each was 2 or 3 mm in diameter.

and over the whole area there was considerable hyperemia of the skin. The pustules, about 5 mm in diameter, were quite discrete and contained a thick yellow pus. No other lesions were seen on the body, the most proximal being at the level of the wrist.

Diagnosis and Treatment—Since the patient had been treated by a number of general practitioners and dermatologists without success, and he manifestly showed no indications of allergy, it was suggested that the nature of the infecting agent should be determined if possible. The seropurulent material from the pustules was therefore examined microscopically, and since nothing could be determined by this means the material was plated for culture on infusion blood agar and Sabouraud's mediums. In the latter the inoculum produced no growth, but on blood agar colonies of *Staphylococcus aureus* and a highly hemolytic gram-negative streptococcus were found in about equal numbers as the sole flora.

Early treatment consisted of local applications, which gave no apparent relief. Subsequently an autogenous bacteriophage antigen was prepared from the staphylococcus. Very small increasing doses were given at daily intervals for four days, then every second day, and finally once each week. Improvement after the first small dose was quite noticeable and subsequent improvement was highly satisfactory with the rapid disappearance of the lesions. However, the vesicles continued to make their appearance but instead of continuing on to pustulation they merely dried up. Three weeks after he received the first dose of bacteriophage antigen, the blisters lasted only over night.

An autogenous vaccine was then prepared from the streptococcus, and minute doses of it were given twice a week, with the resulting complete disappearance of all indications of the infection.

COMMENT

In determining on the method of treatment for this synergic infection, we gave the autogenous bacteriophage antigen with the hope that the nonspecific protein action of the peptone and the lysed culture of staphylococcus would be sufficient to overthrow the immunologic balance maintained between the host and the streptococcus simultaneously with its specific activity in creating more potent antibodies against the staphylococcus. Unfortunately, however, such was not the case, for while great improvement followed the administration of the bacteriophage

Fig. 1—Hands near the beginning of bacteriophage treatment April 19, 1933

antigen, recovery did not occur until after injections of the bacterin prepared from the streptococcus involved.

The appearance of the lesions after they ceased to become pustules gave the impression that the streptococcus was the primary infecting agent in creating the blisters or vesicles. Such was demonstrated to be the case in subsequent culture of the serous fluid from them. They ceased to become pustules evidently because of the increased resistance to the staphylococcus. This would indicate that the staphylococcus was the secondary infecting organism.

SUMMARY

1 A case of dermatitis of long standing was caused by synergic infection with *Staphylococcus aureus* and a highly hemolytic gram-negative streptococcus.

2 Its origin is indefinite and obscure, though the patient reported playing by a highly polluted creek the day before first noticing the acute onset. This may be significant in conjunction with the gram-negative streptococcus.

3 The infection was only of a seasonal nature, making its appearance in the spring and autumn, and was bipartite, beginning with vesicles which became pustules.

Fig. 2—Appearance April 27, eight days later

4 It was evidently noncommunicable and remained localized on the hands in spite of an apparent opportunity for spreading to other parts of the body.

5 Local applications of antiseptics and disinfectants proved valueless in treatment.

6 Injection with an autogenous staphylococcus bacteriophage antigen caused the pustulation to cease, and the final treatment with autogenous streptococcus vaccine caused a complete disappearance of the infection.

MARKED CREATINEMIA REPORT OF TWO FATAL CASES

CHARLES S. HIGLEY, M.D. AND R. O. BOWMAN, PH.D.
CLEVELAND

Following the discovery of creatinine in normal blood and accurate methods of determination by Folin¹ in 1914, Myers and Lough² demonstrated the value of the blood creatinine in determining the prognosis in cases of renal insufficiency. They pointed out that rise in blood creatinine is a more important sign of renal impairment than either uric acid or urea, since creatinine is more readily eliminated by the kidney than the other products and is endogenous, while the others are exogenous. They stated that "a rise in blood creatinine above 5 mg per 100 cc is of grave prognostic significance and portends an early fatal termination unless the rise is due to some acute renal condition."

The differentiation between acute and chronic renal disease in evaluating the prognostic significance of blood creatinine is important. There have been several cases of marked creatinemia with recovery reported in cases of acute renal disease. Myers³ reported a case of nephrolithiasis with a creatinine of 233 mg and Selman and Linegar⁴ reported a case of severe asthma with accompanying medical shock in which the creat

From the Departments of Medicine and Biochemistry, Western Reserve University at City Hospital.

mine rose to 15 mg. Recently at Cleveland City Hospital we have seen a case of corrosive mercuric chloride poisoning with recovery in which the creatinine rose 243 mg.

We have been interested in the height to which the blood creatinine may rise before death in cases of chronic renal disease. It is generally recognized that blood creatinine values approaching 30 mg or over are rare. Only two cases are mentioned in the literature in which the creatinine approached this figure. Myers and Fine⁵ mention a creatinine of 333 mg and Gettler and St George⁶ mention one of 42 mg. At City Hospital, by means of the Myers modification of the Folin method,³ a total of 1 652 blood creatinine determinations were performed in the past thirty-three months. The majority of

these were in cases of known renal insufficiency. Only six of the determinations were above 30 mg and represented determinations in only two cases. There were thirty determinations with values between 20 and 30 mg, representing determinations in eleven cases. All of these cases terminated fatally with the exception of the case of mercuric chloride poisoning.

Two cases of marked creatinemia in patients with chronic renal disease are here reported, both having been thoroughly studied during their clinical course and post mortem.

REPORT OF CASES

CASE 1—R. R., a Negro aged 27 had arteriolar nephrosclerosis diagnosed clinically and confirmed at autopsy. Death was due to uremia and a terminal bronchopneumonia.

The patient was able to be up and about the ward until November 5, when his creatinine value was 22.2 mg (table 1). At that time he developed convulsions and was confined to bed. This case is of interest because of the lack of clinical signs proportionate to the blood chemistry observations and illustrates the prognostic value of the blood creatinine. In spite of the paucity of subjective symptoms the marked rise in creatinine prophesied an early fatality.

CASE 2—R. G., a white woman aged 46 had chronic glomerulonephritis, diagnosed clinically and confirmed at autopsy. Death was due to uremia and a terminal bronchopneumonia.

This case is of interest because of the high antemortem blood creatinine value and because it again demonstrates the prognostic significance of the blood creatinine. The patient felt well enough, February 21, with a creatinine of 10.3 mg (table 2) to insist on release from the hospital. She returned, April 3, and the course was progressively downhill.

CONCLUSIONS

Blood creatinine is an important aid in determining prognosis in cases of chronic renal insufficiency, regardless of the patient's general condition. This fact is demonstrated in the two cases reported.

A SIGMOID ASPIRATOR

WILLIAM Z. FRADKIN, M.D., BROOKLYN
Assistant Surgeon, Jewish Hospital of Brooklyn

To facilitate the method of obtaining rectal or sigmoidal contents in patients suffering with intestinal disorders, a sigmoid aspirator has been devised. The instrument is 8 inches

Fig. 1—Barrel of aspirator

long and three-fourths inch in diameter. It is composed of a barrel and an obturator. Both present four openings, each one-sixteenth inch diameter about one inch from the distal end. These openings correspond with each other when the obturator is inserted into the barrel. The obturator consists of a hollow tube, the distal end of which is enlarged in order to fit accurately into the distal end of the barrel. The proximal end of the obturator presents a lock mechanism and also a well

Fig. 2—Obturator of aspirator

ground tip, which is made to fit an ordinary Luer syringe. The openings in the barrel may be opened or closed by rotating the obturator at R. Figure 1 shows the barrel. Figure 2 shows the obturator with lock mechanism. Figure 3 shows the instrument with Luer syringe attached.

TECHNIC

The sterilized closed aspirator is well lubricated and inserted into the anus. The patient is told to breathe deeply while the instrument is passed gently into the rectum for four

Fig. 3—Sigmoid aspirator with Luer syringe attached

or five inches. No force should be used when passing the instrument. The syringe is attached R, is turned to the open position and the plunger is gently withdrawn. If no fluid appears the instrument is rotated or about 10 cc of air or sterile fluid is injected into the bowel. This will cause a free flow of intestinal contents into the syringe.

ADVANTAGES

The sigmoid aspirator offers the following advantages:

1. The specimen is collected rapidly with simplicity and cleanliness.

From the Pathology Department, Jewish Hospital of Brooklyn.
The instrument is manufactured by George Tiemann & Co., New York.

SOLUTION LIVER EXTRACT CONCENTRATED-LILLY—A sterile aqueous solution containing the nitrogenous nonprotein fraction G of Cohn preserved with 0.5 per cent phenol. Each cubic centimeter contains the active material derived from 33.3 Gm of fresh liver.

Actions and Uses—Solution liver extract concentrated-Lilly is proposed for intramuscular injection in the treatment of pernicious anemia. Its potency is such that the injection of 3 cc per week will maintain the average pernicious anemia patient at normal red blood cell count level. A comparable result may usually be obtained by the ingestion of from 1,400 to 2,100 Gm of fresh liver weekly.

Dosage—For the average patient in relapse, 3 cc is given daily for three successive days, then 3 cc is given at weekly intervals until sufficient time has elapsed in which to observe the response. Thereafter, either the volume of the dose or the time interval between doses is adjusted according to the individual patient's needs.

Manufactured by Eli Lilly and Co., Indianapolis U. S. patent applied for No. U. S. trademark.

Amplex Solution Liver Extract Concentrated Lilly 10 cc Each cubic centimeter contains the active material derived from 33.3 Gm of fresh liver.

To prepare solution liver extract concentrated Lilly livers from edible animals are ground directly into water and the mixture adjusted to the iso-electric point (approximately pH 5 to 6). The mixture is then heated to coagulate protein (approximately 80°C) stirred for thirty minutes and filtered. The filtrate is reduced in vacuum to a small volume and enough alcohol added to produce a concentration of 70 per cent. The 70 per cent alcohol solution is then chilled and the resulting precipitate discarded. The filtrate is reduced in vacuum to a small volume, added to several volumes of alcohol and the precipitate separated therefrom. The precipitate is dissolved in water and filtered. The volume is adjusted so that each cubic centimeter represents material derived from 33.3 Gm of fresh liver. The solution is sterilized by boiling and then passed through Berkefeld filters. 0.5 per cent phenol is added as a preservative.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH Secretary

BARD PARKER FORMALDEHYDE GERMICIDE OMITTED FROM N N R

Bard Parker Formaldehyde Germicide (Parker White and Heyl, Inc., New York) is a mixture of formaldehyde alcohol, and other undeclared ingredients recommended for use in sterilizing steel surgical instruments and rubber catheters that would be injured by boiling water. It is not recommended by the firm for the sterilization of silk or gum woven catheters, cystoscopes, or other instruments having parts soluble in alcohol or affected by formaldehyde.

In 1929 the Council, after consideration of the product, included it in the list now designated 'List of Articles and Brands Accepted by the Council but Not Described in N N R'. When the period for which the product was accepted expired at the close of 1932 the Council adopted a report of the referee recommending reacceptance (1) provided the firm submitted acceptable evidence that the solution kills vegetative and spore forms of pathogenic bacteria in the crevices, joints and interiors of the types of instruments for which its use as a sterilizing agent was being recommended (2) provided the firm declared the complete composition of the preparation on the labels and in the advertising, and (3) provided the firm revised its advertising and labels according to the rules and the evidence found to be acceptable.

A statement of the Council's action was transmitted to Parker White and Heyl, Inc. since that time the firm has repeatedly expressed willingness to cooperate with the Council.

However although a year has passed, it has not made the product acceptable by meeting the objections raised by the Council. The firm has stated that it has approached university authorities to secure the services of a competent bacteriologist to carry out the tests required by the Council and asked (Oct 30, 1933) that "the entire matter be held in abeyance pending the completion of such tests." The questions relating to the substantiation of the germicidal claims could be settled within a few weeks by any competent bacteriologist who undertook to carry out the tests, provided he were given the necessary supplies, instruments and material, but no report of any such work has been submitted, although the firm has repeated its expression of desire to cooperate and its request for postponement of the Council's consideration of the product.

Parker, White and Heyl, Inc., has not indicated its willingness to comply fully with the Council's rule that the essential ingredients be declared on the labels and in advertising. The firm wishes to withhold information on a rust-inhibiting substance in this mixture which may be potassium nitrite, but has offered to give the Council confidential information on this subject. The Council, of course, cannot accept confidential information. In addition, the proportions of formaldehyde, butyl alcohol and ethyl alcohol in the mixture have not been openly declared, although the firm states that it is willing to do so.

In view of the fact that a year of negotiation has not accomplished compliance with fair and reasonable requirements which have been applied with leniency, and in view further of the fact that the firm's noncompliance would otherwise mean retention in New and Nonofficial Remedies of a semi-secret preparation with unsubstantiated claims the Council voted to omit Bard-Parker Formaldehyde Germicide from the List of Articles and Brands Accepted by the Council but Not Described in N N R.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

JELKE GOOD LUCK FRENCH DRESSING

Manufacturer—John F. Jelke Company, Chicago

Description—An emulsion of cottonseed oil distilled vinegar, sucrose, water, spices (paprika, mustard, onion), salt and tragacanth (U. S. P.).

Manufacture—Formula proportions of the ingredients are thoroughly mixed, homogenized and automatically filled into bottles.

Analysis (submitted by manufacturer) —

	per cent
Moisture	39.6
Total ash	4.0
Sodium chloride	3.8
Fat (ether extract)	35.5
Protein (N X 6.25)	0.6
Reducing sugars as invert sugar	2.1
Sucrose (copper reduction method)	16.0
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	18.7
Titratable acidity as acetic acid	1.3
Lipoid phosphoric acid (P O)	none
Total phosphoric acid (P O)	trace
Added color	none

Calories—40 per gram 114 per ounce

HEINZ STRAINED TOMATOES

Manufacturer—H. J. Heinz Company, Pittsburgh

Description—Strained tomatoes retaining in high degree the natural vitamin and mineral content.

Manufacture—Specially grown and selected ripe tomatoes are trimmed, washed and scalded, the juice and more tender portions of the pulp are forced through a screen to remove

seeds and coarse fibrous material. The strained material is concentrated to half its original volume by boiling in absence of air and is subjected to a "vacuum" filled into lacquer lined cans, sealed under "vacuum" and processed.

Analysis (submitted by manufacturer) —
